One of the distinct services of the League has been to inspire doctors of other states to organize along the lines of the "California Plan." Responding to repeated invitations from leading doctors of Oregon and Washington representatives of the California League went to those states some years ago, held conferences, addressed the doctors of Seattle, Bellingham, Tacoma, Spokane, Yakima, Portland, and other places and started their leagues. Doctors from many states regularly visit the League office and receive practical illustrations of how the "California Plan" produces results. California, because of its composite, cosmopolitan, changing citizenship, its great area, embracing all climates the year round, has more new and complex problems, "hold-overs" brought here from other states, than any other place. It is the greatest experimental field for health and anti-health movements of all kinds. Health insurance skipped all the other states and came to California, anti-vivisectionists selected California for their first statewide campaign, and the anti-vaccinationists followed suit. It is observed that where good grain grows profusely weeds will also flourish.

The California League is often called upon and is always glad to give counsel to other organizations, but it assumes no responsibility and believes that all should settle their local troubles according to their own devices. It is obvious that in the last analysis each state must work out its own salvation. No plan or method of organization is automatic or will work uniformly under different conditions with changed personnel. It is proverbial that doctors disagree, but in California this proverb is disproved.

For those who may wish to look upon the darker side of the picture I answer the question, "Has the League no faults and no enemies?" Surely. It is made up of human beings, and to err is human. No human organization can function with 100 per cent efficiency at all times. The best surgeons do not cure all their patients, and every doctor loses fights for the lives of patients, and scientific medicine is confronted with many problems it has failed to solve. If the League were composed of steel parts it might function automatically. But a machine is not open to suggestions, and the League is always. It is safe to say that the League officials are more aware than their critics of the measure by which they fall short of perfection. It is absolutely safe to state that they would welcome nothing better

than constructive help and suggestions to enable the League to render better service.

EIGHT YEARS OF PRACTICAL WORK

The League has opposed and defeated very active groups. It has made enemies as well as friends, because it does so much. All the cults are unanimously against it, some hospitals that prefer to run loosely, others who dwell in the twilight zone and officials and politicians who want to be half-quack and half-scientific to get the votes of all, and a few who do not understand why the practical every-day work of the League is necessary, because they themselves are such successful doctors and have "arrived" and are not troubled by or interested in the problems of those who are only on their way or just about to start. It is a common fault of successful men in all walks of life to play lone hands and let the devil take the hindmost. It is pleasant, therefore, to say that most of the work of the League is done by men whose position in medicine and in the community is assured, whose practices and income are large and who are dedicating part of their time to this public service with no personal or selfish purpose whatsoever. They give up a lot of time to League work, dig up information, articles for the press, iron out troubles of different groups, help elect better legislators and other officials, keep abreast of things that are happening on questions that affect directly or indirectly the field of medical practice, give a helping hand to the younger men and pay their own good money for the privilege of serving others. With such examples of service, we may look with confident optimism to the future of the League. The officers and personnel of the League, on the whole, constitute a body of men and women in whose ability and integrity the public and the profession can place trust and confidence.

What one finds in the final summing up is, the "California Plan" of the League for the Conservation of Public Health has aroused other organizations in other states to a larger sense of leadership and public responsibility. Eight years of service in California have proven its practical value in constructive publicity, in better health service, in hospital betterment work, in promoting good measures and movements, and preventing bad legislation. The ideals and spirit of co-operation of the League and its conceptions of public responsibilities are fundamentally sound. The process by which it has developed and carried on its varied activities is a gradual one, but it is, nevertheless, sure. Its influence in moulding a healthier public opinion for the benefit of all worthy health agencies is growing greater and more extensive. Its scope of service has broadened and bettered each year. It is a very busy organization with daily work that counts for steady progress. It is giving every worthy work valuable publicity except its own. It is too busy with much serving to tell us its own story, and that is what prompted me to review some of the important work of this unique organization. The League's record reflects great credit upon the ability and willingness of the doctors of California to work together for the common benefit of the public and the profession.

THE MEDICAL PROFESSION AND THE MEDICAL OFFICERS' RESERVE CORPS

By W. E. MUSGRAVE, M. D., *San Francisco*

THE National Defense Act, approved June 3, 1916, and as later amended, establishes the Army of the United States, the components of which are (a) the Regular Army, (b) the National Guard while in the service of the United States, and (c) the Organized Reserves.

Under this law, all Reserve units—including Medical Department units—after being organized become part of the permanent defense forces of the United States. As such, they are destined to share in whatever military operations and successes may be engaged in by the nation in the future. A Reserve general hospital allocated to California, for example, has the same permanency of history and function as a regiment of Regular Army cavalry at Monterey, or an infantry regiment of the California National Guard. The same need for their organization and maintenance dominates them all, and is an obligation laid by the nation at large on each local community. So far as the personnel and units of the Medical Department are concerned, they represent a definite obligation laid by the nation upon the medical profession of such communities.

The Regular Army has its duties in peace as well as in war. The National Guard may be called out by the state authorities in case of local trouble, or in a national emergency by authority of the President. The Organized Reserves can only be called out in a national emergency declared by Act of Congress. *In the latter case, the man-power of the nation generally can and will be called out, whether it belongs to the Organized Reserves or not.*

In general terms, the Regular Army and National Guard represent the first line of defense; the Organized Reserves represent the second line of defense. Behind these combatant lines, the bulk of the burden falls on Reserve personnel and Reserve units.

The latter fact is particularly true in respect to the Reserve Medical Department. The Regular Army has its few fixed hospital establishments, adequate for its own needs in time of peace, but susceptible of only limited expansion in time of war. The National Guard has its medical service attached to troops, but no provisions for hospitalization. The Organized Reserves, through the Medical Officers' Reserve Corps, are expected to meet not only Organized Reserve needs generally, but the hospitalization, and other needs back of the combat zone, for an expanded Regular Army and the eighteen Divisions of the National Guard as well.

The maximum effort under the National Defense Act calls for the raising of 6 Field Armies, which include 9 Regular Army Divisions, 18 National Guard Divisions, and 27 Reserve Divisions. Besides these 54 combatant divisions, the plan calls for a large number of special troops, and the co-ordinate organizations and establishments of special branches. The total personnel required for these six Field Armies is approximately 4,000,000 men, all of which are to be raised within one year.

The part which the Medical Department is called upon to fill in this vast general plan of defense is

very great. Its required personnel will aggregate over 500,000—officers, nurses, and enlisted men—and this personnel will handle hospitals aggregating some 400,000 beds. The minimum officer requirements to be provided for the Medical Department are 43,156; of which 30,783 are medical officers, 5188 are dental, 2766 are veterinary, and 4419 are medical administrative and sanitary.

The raising of this force is apportioned among the states of the Union according to their military manpower, and these states are grouped, for purposes of military administration, into Corps Areas.

The Corps Area of local interest is the Ninth Corps Area, which includes the states of California, Nevada, Utah, Wyoming, Montana, Idaho, Washington, and Oregon, and the territory of Alaska.

The Reserve medical problem allocated to this Ninth Corps Area includes the raising of 2050 medical officers of the Medical Department and their organization into specific medical units.

The last medical directory shows the number of physicians licensed to practice in the above states and Alaska to be 12,443. Out of this total, 2050, or 16.5 per cent, are required for the Medical Reserve Corps. If all states furnish Medical Reserve officers in proportion to their licensed physicians, their respective quotas are shown in the following table:

State	Physicians registered	Medical Reserve Officers required
California	7,549	1,243
Nevada	140	23
Utah	497	82
Wyoming	263	43
Montana	568	94
Idaho	452	75
Washington	1,756	289
Oregon	1,158	191
Alaska	60	10
Totals	12,443	2,050

While many branches of the service can and will enroll officers from any or all walks of civil life, only the medical profession can furnish medical officers. Its part cannot be confused or misinterpreted. The number of physicians who actually enroll themselves in the above states will clearly evidence the relative degree of patriotic and professional interest therein.

The fundamental patriotism of the medical profession at large was abundantly shown in the last war. Physicians then enrolled for service by the tens of thousands, often at great personal sacrifice. For enrollment now in the national defense no sacrifice is now required. No duty is asked which the Reserve medical officer may not wish to give. All that is required is that the physician be willing to serve his country in national emergency, and, in the meantime, to lend his name and influence to the building up of effective medical organizations, fit for prompt service in case of such emergency.

If in the meantime he desires to be in line for promotion, he has the opportunity to fit himself by correspondence course training, or by attendance at summer camps, for the duties and responsibilities pertaining to the higher grades open to him.

The matters of appointment and promotion in the

Medical Reserve Corps are governed by Army regulations. Former officers in the World War; physicians who contributed to the success of the war by service on the Council of National Defense, as a draft examiner or a member of draft board; a former officer of the Navy or Allied Armies, or who was connected with essential public establishments as educational institutions, hospitals, public health organizations, or was a public administrative officer, may be originally appointed in a grade commensurate with his age and standing in civil life. Others enter as first lieutenants and are promoted by regular steps in gradation to fill vacancies for which they are qualified. *Rank is not an index of professional ability, but of competency in a military sense.*

That there shall be appropriate gradations in age and experience as well as rank, Army regulations require the following periods of service, by grade, of qualified officers: As first lieutenant, two years; as captain, five years; as major, five years; as lieutenant-colonel, three years. A young physician entering the lowest grade could thus be promoted into the grade of colonel, with command of the largest medical units, in the short space of fifteen years—or a little more than half the time it takes for a medical officer of the Regular Army to reach that grade and command.

Medical service may be defined as "combat" and "non-combat" service. "Combat" medical service is that performed by medical officers directly attached to combatant troops. It is usually of an emergency nature and not professionally definitive. "Non-combat" medical service is that performed in units not attached to combatant troops, and often far in the rear of the lines of defense. It gives definitive medical treatment and professionally approximates the work of the medical practitioner in a civil community. In round numbers, the assignments of medical officers as to these divisions of service represent about one out of four for "combat" service, and three out of four for "non-combat" service. Whichever type of service is chosen depends on the personal preferences of the individual medical officer.

At present, the need for Medical Department officers particularly relates to "non-combat" units. Within the Ninth Corps Area, a total of eighty-one such units are required. Some idea of their nature and numbers may be inferred from the fact that the following totals are required: Three hospital centers; 14 general hospitals; 10 evacuation hospitals; 15 station hospitals; 8 surgical hospitals; 8 hospital trains; 5 medical laboratories; 1 army medical laboratory; 1 medical supply depot; 1 convalescent hospital; 2 corps medical services; 2 medical regiments; 1 veterinary convalescent hospital; 3 veterinary evacuation hospitals; 2 veterinary station hospitals; 7 veterinary general hospitals. To staff the foregoing units with medical officers, alone, will require a total of 1214 such officers.

The foregoing units have been apportioned to states within the Ninth Corps Area, and within states they have ordinarily been assigned home stations at large centers of population. The allocation of these units is as follows:

California, 43; Oregon, 15; Washington, 12; Utah, 4; Idaho, 3; Montana, 3; Wyoming, 1; Nevada, 0.

In assigning an officer to a unit and duty, his preference and that of the commanding officer of the unit considered are habitually consulted. The general considerations for assignment are that the unit is located in the community or vicinity of the residence of the officer concerned, that an appropriate vacancy exists in the unit for a man of his technical qualifications, and that such assignment would be acceptable to all concerned. The latter point is more important in a Reserve unit than any other. Regular Army, and even National Guard units, have a more or less rapid turnover of personnel. *But the personnel of a Reserve medical unit established in a community, and officered by the physicians of that community, will, except for death, and ordinary casualty, remain largely unchanged and permanent in its make-up of personnel.*

In time of peace, no Medical Reserve officer can be ordered out for a longer period than fifteen days for training in any one year. Any objection that this might some time be inconvenient is purely hypothetical. Funds are not available to send to training camps more than a very small percentage of even the present enrollment. As a matter of fact, they are not sufficient to send to training camps more than a fraction of those who apply for the privilege. Those who are thus ordered out, of course, receive the pay and allowances of their grade while so serving, and those who have attended such training camps have been enthusiastic over their interesting and enjoyable experience. *But whether an officer goes to training camp or not depends upon his own desires.*

As to service, in time of war declared by Congress all Medical Reserve officers will be ordered to the colors. So, too, will the medical profession at large under the draft law. The Medical Reserve officers, who already have commissions of high rank and positions of authority, will be in command of the late-comers.

There are physicians who have not yet enrolled in the Medical Reserve Corps, thinking that it would be sufficient for them to offer their services in time of war. Such delayed action is not the full measure either of patriotism, humanitarianism, or self-interest. In respect to patriotism, such delay stands in the way of the desired development by the nation in advance, of the organizations which will be sorely needed immediately on mobilization day itself, to care for the illness and injury incident to aggregations of men. As to humanitarianism, delay up to the eleventh hour means that the nation's defenders in the first line will not receive that efficient, systematized medical and surgical aid to which they are entitled. From the standpoint of the self-interest of the individual, it means disappointment. *The draft will become effective, medical men needed will then be enrolled without the privilege of volunteering, and they will be given such lower rank, status and professional assignments as conditions may warrant. In other words, they will take what is left, irrespective of their prior good intentions and professional standing in civil life.* Medical officers who have helped to build up the nation's relief establishments in time of peace, and who have tried to prepare themselves for their duties in connec-

tion therewith, will not be displaced from positions of rank, authority, and professional congeniality in order to meet the desires and personal interests of belated patriots.

As to who should enroll in the Medical Officers Reserve Corps, there is need and place for any practicing physician who can satisfy the physical and other requirements. The service is of such nature that general practitioners are essential. Likewise, with units of such diversified nature and function, specialists in all the major professional specialties are required.

The older men, and especially the veterans of the last war, are needed to lend their prestige and experience to the creation of these great relief organizations, and to ensure their proper development and smoothness of operation. Their patriotic assistance will very likely take no further shape than a contribution to preparedness.

Younger men of the coming professional generation are needed to round out these organizations, to maintain them, and to succeed to their control. Future actual medical emergencies must be met largely or wholly by medical personnel of the future. It devolves on the younger professional generation to take the colors from weakening hands, and press forward.

Medical men who enroll in the Reserve Corps in advance of emergency are assured of rank, steady promotion as they demonstrate fitness for it, increased pay and authority, an assignment to such professional duty as they are best qualified to perform, and association with a congenial unit made up of friends and neighbors of their home communities.

In so enrolling, they are rendering a great humanitarian, as well as patriotic service. They are helping the nation to prepare for its needs in an hour of extremity. They are helping to avert unnecessary suffering from its future defenders. They are helping the medical profession to avoid many of the general and personal difficulties it experienced in the last war, lending their aid to the plan for medicomilitary preparedness.

THE TIME HAS COME FOR THE MEMBERS OF THE MEDICAL PROFESSION TO STAND UP, BE COUNTED AND, AS MEMBERS OF THE MEDICAL RESERVE CORPS, TO COME TO "FRONT AND CENTER."

"There are some forms of propaganda issued in support of the periodic health movement which would lead the readers to believe that preventive medicine and public health movements originated outside the profession and were being forcefully thrust upon physicians, as part of their citizenship duties.

"The author of these apparently has never heard of the Hittite inscription that appears on the aged temple walls in Cappadocia. As in ancient times, this same inscription covers today the services of the physician. It says:

"*Then Zarthusstra, the Sage, stood forth and spake: 'Go often to your physician, O, people, that you may know yourselves. Some, being in good health, he will instruct, and keep so; some have beginning maladies—these he will make whole; some have illnesses—these he will help or cure; some are beset with dire diseases which exist not except in imaginings—these he will reassure.'*" (Ohio Med. Jour.)

PRESIDENT'S ADDRESS, UTAH MEDICAL ASSOCIATION *

By SOL G. KAHN, M. D.

ELECTED to the highest office in the power of this Association to bestow, I am deeply sensible of the sincere compliment you have paid me and of the great trust you have placed in my hands, and I wish to assure you of my appreciation of this mark of your favor, this evidence of your confidence. I wish also to thank you and my associates in office for the efficient co-operation and active support which have been accorded me, all of which will have served to make this, the thirty-first annual meeting of the Utah State Medical Association as successful as its outlook promises.

Great changes have taken place in the period covered by the life of our Association, and we may speak with pride of the achievements in both medicine and surgery during this generation, but I scarcely need remind you of them in detail. Every physician is proud of the record, and happy to live in an age when so much has been done for the comfort and well-being of the human family by the noble profession to which he belongs.

The delivering of an address by a retiring president is an ancient and honorable custom, and frequently consists of many words and consumes much time. Since "brevity is the soul of wit" and "tediousness the limbs and outward flourishes," I will not, I trust (after the same manner as Shakespeare's Polonius) "be brief," nor shall I attempt to be witty.

A few topics must be outstanding ones in my talk:

First, Change of Time of Meeting—In the hope that the general interest in the work of the Association might be promoted, your officers and committees, gentlemen, have seen fit to make certain changes in the scientific program for the meeting this year. Instead of breaking into two weeks, it was decided to combine the time of the committees scientific work, and education and post-graduate work into one week of intensive study and application. This also gives us the benefit and pleasure of having here at our meeting the medical men who come from outside the state to give our post-graduate work. We hope this innovation will meet with your approval and that the experiment may prove a success.

Second, the Matter of the State Board of Health—It is gratifying to note the increasing spirit of co-operation between the medical profession and the State Board of Health. There can be no question as to the physicians' importance in the public health program, and it should be their duty to acquaint themselves with the work and aims of the health officials who may be depended upon to welcome their co-operation and assistance.

These facts were especially demonstrated in the recent goiter survey of the State Board of Health.

In another instance, our advisory committee to the University was able to aid in the correction of

* Delivered at the banquet of the Thirty-first Annual Meeting of the Utah State Medical Association held at Hotel Utah, Salt Lake City, Utah, September 8, 1925.

a situation where public health interests were involved. For many years the bacteriological laboratory had been located at the University of Utah, where examinations were made when authorized by the State Board of Health. For reasons that need not be discussed here, the service was unsatisfactory alike to the Board of Health, the medical profession, and the University. Dr. Beatty, executive officer of the board, finally prevailed upon the International Health Board to fully equip a laboratory in the State Capitol, and steps were immediately taken to effect its installation.

Objection was raised by some of the University authorities to the taking of the health work away from the University laboratories. The Advisory Committee, in behalf of harmony, studied the situation and favored the change.

Dr. George Thomas, President of the University, then introduced a bill into the legislature, which was enacted, repealing the law which authorized the University to provide public health laboratory service.

With entirely new and complete equipment, and in charge of a bacteriologist of high standing, the laboratory is now furnishing prompt and efficient service, which is available free of cost to all physicians of the state, when called upon, to assist in the diagnosing of communicable diseases.

The policy of the State Board of Health is, to the full extent of its power, to render laboratory service that will promote the public health. Purely clinical laboratory work will not be done except in the case of indigents.

Third, Medical Ethics—Medical ethics is having a difficult time during the present era of commercialism. I learn from recent graduates that medical ethics is, in most medical schools, taught in a perfunctory manner or not at all, and from my experience on the committee on Public Health and Legislation for the Salt Lake County Medical Society the past two years, I feel that more stress should be placed upon "the treatment one gentleman should accord another." It might be well for the State Association and the County Societies to take this matter up for discussion once a year so as to familiarize all concerned with the usage, the practical application and the benefits of a few of these old practices. Many men profess to practice a specialty and yet take all classes of cases that come to them, which is neither ethical nor fair. It creates enemies, disrupts the profession, causes the laity to lose faith in us, and lowers the standing of the real specialists. Specialist is a term which, according to the dictionary, means "one who devotes himself to some specialty." Let us try to live up to the definition and not claim to be something we are not.

Then, too, many young men are rushing into the specialties without proper preparation, either by virtue of having practiced general medicine for a number of years and then devoting two or three years to perfecting themselves for the particular specialty, or by having training as an assistant for a number of years. An examination by a board, similar to that conducted by "The American Board of Ophthalmic Examiners," or "The American Board of Otolaryngology" should be the determining factor in establishing a specialist's claim to his title and prac-

tice. In the same connection might it not be suggested that specialists to whom general practitioners recommend patients, adhere strictly to their particular line of work? The ethical code, though concise, seems not to be thoroughly understood by some.

Fourth, Malpractice—A shrug of the shoulders, an elevation of the eyebrows and the attitude of "well" appears to continue to obtain with some physicians regarding this subject, as evidenced by the fact that we are still having malpractice suits. No malpractice suit can be carried on or even started without some M. D. lurking in the rear of the battlefield and supplying the ammunition. Let us watch ourselves with greater care each succeeding year, and when people who have been treated elsewhere come into our office let us attend strictly to our own affairs and be like the

Wise Old Owl that sat on an oak
The more he saw, the less he spoke;
The less he spoke, the more he heard,
Let us all be like that wise old bird.

Opportunely, come to mind the oft-quoted lines:

If you your lips would keep from slips,
Five things observe with care:
Of whom you speak,
To whom whom you speak,
And how, and when, and where.

Official Visits—Your officers have made an official visit to five of the seven constituent societies during the year. Harmony and good feeling seemed to prevail among the members of the profession in our state. We regret our inability to call upon the Carbon and Uintah county societies. We feel confident, however, that the next administration will make a special effort to pay them a visit.

May I Make Some Suggestions?—I have two suggestions to offer which I consider of importance. One was presented to the House of Delegates at our last meeting and received unfavorable consideration. However, I feel that by a little further discussion and consideration by all members of the Association, it will meet with approval. This suggestion is to pay a part of the expenses of our delegate to the annual meeting of the A. M. A. The sessions of the A. M. A. are usually held in the East and the expense, to say nothing of the expenditure of time, is too great for anyone to incur annually over a period of years. A delegate who attends one session rarely knows what it is all about until the session is over. In order to be of value to the Association a man must have an acquaintance and be familiar with the routine. This cannot be accomplished, except in rare instances, unless one has attended several meetings. No delegate from this Association has ever attended two or three successive sessions. I attended several during my incumbency, but never two in succession. If we were to set aside \$100 or \$150 to assist in defraying the delegate's expenses, I feel we would meet with better success, because the longer a man is a member of the House of Delegates of the A. M. A. the more valuable he becomes to both the A. M. A. and to our own Association. There are men who have been in the House from ten to fifteen years and they are a power.

The other suggestion is that we have a nominat-

ing committee of five (no two to come from any one constituent society) and that we do not depend upon spontaneous combustion to nominate and elect our officers.

The introduction of the next theme I should like to discuss may appear irrelevant, but I feel that it concerns so nearly the fate of our youth and the necessarily active part we are called upon to take in the preservation of life, that I have conscientiously incorporated it in my address.

Rev. Stanley A. Curtis, in a lecture on Americanism delivered on April 17, 1924, at Salt Lake, stated that in a recent visit to the Juvenile Court he learned that they had just caught the bootlegger who supplied booze to the students at the East Side High School, and that they were hot on the trail of the bootlegger who was supplying bootleg to the students of the Junior High; that they were both aliens and that what we needed was not so much restriction on immigration, but a few boatloads of emigration. While we do not wish to mix in politics, as that is not our province, we *do have* the young manhood and womanhood of our great land as our particular charge. We know from our daily experience that the boys and girls of high schools consider it a great lark to pass a bottle of moonshine around. We are also familiar with the results of many of these so-called larks. I feel we should raise our voices in protest against anything which has a demoralizing influence upon children. If we follow the suggestion of Mr. Curtis and do something to see that any alien who supplies bootleg to students is deported, we are only performing our duty.

While many of us (and I among them) do not sympathize with the workings of the eighteenth amendment, we are strongly opposed to school boys and girls indulging in intoxicants. I, therefore, suggest that we request either the A. M. A. or our representatives in Congress to introduce an amendment that any alien caught supplying bootleg to school children be deported, and any American caught doing the same be put in Leavenworth for not less than ten years.

Permit me to thank you all again for your great kindness, forbearance and courtesy and for honoring me with your confidence. Allow me to close my remarks with my most cordial good wishes and repeat to you a quotation which has but recently come under my notice. It is from Robert Louis Stevenson's *Dedication to the Underwoods*:

"There are classes of men that stand above the common herd; the soldier, the sailor, and the shepherd not infrequently; the artist rarely; rarer still, the clergyman; the physician almost as a rule. He is the flower (such as it is) of our civilization; and when that stage of man is done with, and only remembered, to be marveled at in history, he will be thought to have shared as little as any in the defects of the period and most notably exhibited the virtues of the race. Generosity he has, such as is possible to those who practice an art, never to those who drive a trade; discretion, tested by a hundred secrets; tact, tried in thousand embarrassments; and what are more important, Herculean cheerfulness and courage. So it is that he brings air and cheer into the sick-room and often enough, though not so often as he wishes, brings healing."

POLIOMYELITIS

The San Francisco County Medical Society recently devoted one of its sessions to a symposium upon this very important subject. California and Western Medicine has not the space to give all of these four papers in full, but we did offer to publish abstracts of all of those that were sent in in time for our November issue. Abstracts as given below have been received.—EDITOR.

PUBLIC HEALTH ASPECTS OF POLIOMYELITIS

By GEORGE E. EBRIGHT, M. D., *San Francisco*

THE writer called attention to the following points:

It has never been possible to enforce a law that is not approved or not understood by the people whom it affects, and health regulations are of no avail unless supported by a sufficiently strong public sentiment in their favor. The most potent single factor in creating proper public sentiment that shall operate in the control of preventable disease is the influence that may be wielded by the individual physician.

Important factors concerned in the dissemination of poliomyelitis are not yet clearly known, especially the role of healthy human carriers.

The paper traces the history of the disease, beginning with early Egyptian times down to the present moment, and refers to its experimental production in monkeys, the recognition of a filterable virus, the presence of immune substances in the blood of convalescents, the diversity of virulence of various strains of the virus and recognition of the virus in various parts of the bodies of persons dead from the disease.

A consideration of the fact that immune bodies have been found in 66 per cent of persons who have been in close contact with cases, of the large number of abortive cases, and those showing, during an epidemic, a great diversity of symptoms without paralysis, leads to the assumption that the disease and a resulting immunity is probably infinitely more widespread throughout the population than has formerly been suspected.

Prevention—Patients are to be isolated in the acute stages in much the same way that typhoid cases are, with the similar precautions regarding body discharges.

Nose and throat sprays of antiseptic solutions are useless, in that they do harm in removing a natural protective substance in the nasal secretion which neutralizes the virus of the disease.

The most efficient agency of control of an epidemic is the public health nurse.

The closing of schools is advised against. A study of the 1925 epidemic of poliomyelitis in California showed that the number of cases of the disease was greatest about the first week in August, and in spite of the return of over 200,000 pupils to school at that time, the number of cases in the succeeding two months steadily diminished.

PATHOLOGY OF THE NERVOUS SYSTEM IN ACUTE ANTERIOR POLIOMYELITIS

By CHARLES E. NIXON, M. D., *San Francisco*

The lesions of the nervous system produced by poliomyelitis involve both ectodermal and mesoder-

mal tissues; the most striking clinical feature—the flaccid paralysis—is due to the involvement of the anterior horn cells, but poliomyelitis is not to be considered as a disease affecting the anterior horn cells, or even the anterior gray matter primarily or exclusively, for oftentimes the mesodermal tissues—the pia, blood-vessels, and lymph spaces—are predominantly involved. Neither are the lesions found in the spinal cord alone, for almost every fatal case shows evidences of an extension of the inflammatory process in the brain stem and often, also, to the cerebrum. Many patients have symptoms pointing to involvement of the cranial nerves, and in some the process is essentially bulbar, pontine, or mid-brain, giving pupillary changes, extra-ocular paralysis, ptosis, nystagmus, facial paralysis, or difficult respiration and deglutition. A more accurately descriptive term would, therefore, be acute polio-encephalomyelitis. Whether the polyneuritic-like symptoms are due to a true neuritis or to a posterior root ganglion inflammation or central in origin, is not known. However, the process most commonly involves the lumbosacral region of the cord, and this localization gives the characteristic clinical picture.

The gross changes usually are not very marked, though sometimes conspicuous. There may be noted, macroscopically, hyperemia of the meninges, spinal cord or brain; occasionally there are hemorrhagic and necrotic areas.

Microscopically, the usual picture is an inflammatory process with mononuclear-celled infiltration of the leptomeninges extending into the anterior fissure and along the pial processes and vessels into the cord where there is perivascular infiltration, engorged vessels, glial proliferation, and chromatolysis of the ganglion cells.

ANTERIOR POLIOMYELITIS THE ORTHOPEDIC PROBLEM

By LEONARD W. ELY, M. D., *San Francisco*

From the time when the diagnosis is made, two problems are presented: to prevent deformity, and to secure the maximum amount of terminal function. The amount of residual paralysis will depend upon the extent of damage to the anterior horns of the spinal cord. We have no means of influencing this, except by keeping the patient absolutely quiet. Massage, electricity, and the various other procedures of physical therapeutics are useless. They may be actually harmful in the early stages.

During the early stages our sole purpose is to prevent deformity. Deformity is the result of gravity and of imbalance of muscle. If all the muscles of a limb be paralyzed we have little to fear it, but with the return of some of them to function, active measures of prevention become necessary. If nothing be done, the active muscles shorten and produce contractures and subluxations.

In the lower extremities the most common deformity is a foot drop, from paralysis of the anterior leg groups. The tendency to deformity is increased by the weight of the bed clothes. To forestall this we apply some form of splint. We have little to fear at this time from contractures of other

muscles. The recumbent posture and the bed clothes prevent flexion contractures of the other joints.

As the patient begins to go about, other contractures must be prevented. The treatment at this stage is more active than in the earlier stage. The object is to preserve the full range of motion of the joints in the direction of the paralyzed muscles and to get the greatest possible function by the remaining sound muscles.

After the acute stage of the disease, we get the patient up, and by exercise and training let him learn to educate his remaining muscles to perform their maximum amount of function.

At the end of about a year we shall know about how much permanent paralysis confronts us. In the less extensive cases we may proceed on the same lines. When growth has been attained, the tendency to deformity usually ceases. For cases of medium severity various operative measures have been proposed to stabilize the joints.

Tendon transference is often useful if we know its limitations and understand its technic. It is of little good to perform elaborate operations if the patient cannot use the transferred muscles to move his limbs.

With a paralyzed quadriceps extensor cruris, the patient often learns to super-extend the knee in walking, thus locking it, attaining a fair degree of function. If not, then a stiffening operation is advisable. Operations for stiffening the hip are not usually very satisfactory. For an unstable foot I prefer the Whitman astragalectomy.

Involvement of the trunk muscles may cause a marked rotary-lateral curvature. Its treatment is difficult.

To sum up: In the early stage, rest; in the stage of improvement, prevention of deformity; in the late stage, braces or operation.

TORTICOLLIS

By WILLIAM ARTHUR CLARK, M. D., *Pasadena, Calif.*

Review of the literature.

General discussion of the condition.

The results of operative treatment are very good.

The younger the patient, the better will be the result.

Complete correction and disappearance of facial asymmetry can be expected in children under twelve.

In patients over twenty the change in shape of the cervical vertebra secondary to the long-continued position of deformity may preclude a complete restoration of the normal position.

It is wise to consider carefully before undertaking operation in adults, since there may be obtained only enough correction to accentuate the crooked face, and the patient will consider that he has been made worse instead of better.

DISCUSSION by R. S. Zumwalt, *San Francisco*; John C. Wilson, *Los Angeles*; Lionel D. Prince, *San Francisco*; Walter C. S. Koebig, *Los Angeles*.

THE earliest reference to torticollis which I have found is that of 1641, when Isaac Minnius did an open section of the sterno-mastoid muscle for the relief of this condition. About the same time, Robelais first used the name by which the deformity is known today. Tulpius wrote on the subject in 1650. This, of course, is not very ancient history

in medicine, since it was about 2000 years after Hippocrates and about 1400 years after Galen. Still, it was more than 200 years before anesthetics were used and several years before the first hospital was established in the American Colonies. Minnius was one of those pioneer German surgeons who lived in a time of individual experimenting in surgery, when barbers and surgeons were still undifferentiated.

Not many years later Hendrik van Roonhuyze, who is said to have been the first to practice orthopedic surgery, was doing operations for wry-neck and harelip. Dupuytren, the ablest and best French surgeon of his time, was the first to treat wry-neck by subcutaneous section of the sterno-mastoid muscle. This was in 1822. In 1873 Samuel David Gross of Philadelphia did myotomy instead of tenotomy for lengthening.

Torticollis, or wry-neck, may be structural or functional in character. The structural type may be either congenital or acquired, but most of the cases we see are congenital. Under congenital forms we have the muscular which is most common, and skeletal which is rather rare. The muscular form is due to permanent shortening of the muscles passing from the clavicular and scapular region to the temporo-occipital region, the chief of which, in connection with this deformity, is the sterno-mastoid. The other muscles shortened, probably secondary and to lesser degree, are the trapezius and splenius capitis. The skeletal form may be due to (1) occipitalization of the atlas on one side, (2) synostosis of the atlas and axis, (3) malformations, such as wedge-shaped cervical vertebrae.

Acquired torticollis may also be either muscular or skeletal. Muscle contracture may follow injury especially in early life, but such cases are usually not permanent. Deformity of the cervical vertebrae may result from disease such as tuberculosis and a wry-neck result, but except in a very broad sense of the word this is not a torticollis. Spasmodic contracture of the sterno-mastoid sometimes occurs, usually in adults, causing a torticollis which is functional and intermittent. It comes in the class of habit spasms and occurs usually in neurotic people.

This paper deals only with the structural muscle type.

Among the total number of deformities coming under the observation of orthopedic surgeons, torticollis forms a very small percentage. Only 0.49 per cent occurred among 1444 cases in Hoffa's clinic, 2 per cent and 1 per cent according to others. At the Los Angeles General Hospital I found only three cases in the records of the past five years, and only one of these was a typical torticollis. At the Pasadena dispensary there has been one case of muscular and two of skeletal in the past three years. There seems to be no predilection to sex, but there is a slight majority of right-sided over left-sided cases. Rarely the deformity is bilateral, in which case the shoulders are high, the neck short, and the chin and face point upward somewhat.

The cause of the contracture is not known. Intra-uterine pressure, trauma, ischemia, and infection furnish the basis for various theories. The intra-uterine pressure idea seems most tenable because it

is well known that a muscle adapts its length to the distance between its origin and insertion. If this distance is decreased the muscle shortens itself proportionately. I have recently had an experience which supports this theory. A girl 4 years of age was brought for treatment of a high, right dorsal scoliosis, with right shoulder higher than the left. Soon after the application of a plaster jacket in an overcorrected position, the right shoulder low and the left high, it was noticed that a right torticollis was developing. This gradually increased until the deformity was quite marked, the head in the typical position tilted to her right and rotated to her left. When the patient was put in a permanent leather corset, however, with the shoulders level, the torticollis slowly diminished, and at the present writing, about three months since its appearance, it is scarcely noticeable. The explanation of this seems to be that the right sterno-mastoid and other muscles on the right of the neck were originally shorter than those on the left, due to the higher right shoulder, and when the position of the shoulders was reversed a tension was put on the right side which pulled the head over. If the head of the fetus is held to one side against the shoulder, by pressure of the uterus, it would seem that the muscles on that side would be shorter than those of the opposite side, and when the pressure was released the tension would produce the characteristic deformity. Siffel studied six cases of congenital torticollis in an obstetrical clinic when it was customary to use roentgen ray for diagnosis of position in pregnancy. Four of these had been rayed in utero at five to six months, and an inclination of the head was noticed in all of them. He states that this inclination is more common in breach and transverse positions, and concludes that the subsequent torticollis is due to muscle-shortening, either from arrested development or from inclination of the head in the uterus. Schubert, however, regards the intra-uterine theory as untenable, because the deformity is sometimes associated with other malformations, usually hemilateral, and because of the frequent instances of heredity. He places the origin in a primary disturbance of the central nervous system. Roger and Pourtal found anomalies of the cervical vertebrae in seven out of eight cases, but thinks that these may be secondary and that the true source of the trouble may be in the brain.

The ischemia theory is supported by Meyerding, whose paper is based on a study of twenty-six cases. He regards the condition as a chronic interstitial myositis resulting in ischemia, caused by interference with the blood supply from pressure. This, of course, is analogous to Volkmann's contracture. Eight of his cases gave a history of trauma at birth, which may have resulted in hematoma of the sterno-mastoid and consequent pressure. Other adherents to this theory are Volker, Kempf, Ritter, and Schloesmann.

Mikulicz assumes an infectious origin; a chronic inflammatory process resulting in a myositis. Stroe-meyer's trauma theory has very little support.

The microscopic pathology of the muscle has been studied by Bouvier, Krogius, Volkmann, Mikulicz, and others sufficiently to establish the character of the muscle change. There is a substitution of fibrous connective tissue for muscle, sometimes almost total

replacement, producing a fibrous band. The muscle fibers which are left have lost their cross-striations.

Symptoms are almost all objective. There is usually no pain or discomfort. The objective signs in the typical case are inclination of the head toward the side of the contracted muscle, and rotation of the face and chin toward the opposite side. This is purely a mechanical result of the muscle pull. The skull as a whole acts as a lever in its antero-posterior line, the fulcrum being at the articulation with the atlas, the power end at the occiput, and weight end in front. The sterno-mastoid insertion is on an elongated area beginning at the mastoid process and extending posteriorly, about one-fourth being on the occipital bone. The pull of this contracted muscle, then, is practically all posterior to the atlas articulation, which, of course, throws the other end of the lever (the face) in the opposite direction.

The facial asymmetry, which is present in most cases of long standing, is explained by retarded development of the skull on the contracted side, probably as a result of relatively poor blood supply. The eye is lower and the entire vertical length of the face is shortened on the affected side. Close observation will show that there is a broad vertical curve in the face, the concavity on the affected side. It has been shown in some cases that on the affected side the carotid artery is actually smaller than on the other side. Other theories which seek to explain the facial asymmetry are atrophy of disuse and irregularity in fusion of ossification centers in the skull. This asymmetry tends to disappear after the torticollis is corrected if the patient is not too old. Immediately after correction, however, it is more noticeable because it looms up in contrast to the new straight position of the head. The patient and parents should be warned of this beforehand.

Diagnosis of muscular torticollis is not difficult with an obvious contracture which is easily seen and felt. Occasionally one sees a case in which no contracture is present, and then attention should be turned to the cervical spine. It should be carefully studied by roentgenogram, as well as clinically, for evidence of anomaly or disease. A tubercular spine would, of course, be limited in motion in all directions by muscle spasm. In such a case the chin points to the same side as the inclination of the head. The same is true for any other form of arthritis in the neck. If the spine is found normal the cervical lymph nodes should be examined for inflammation, the eyes for defects in vision, the ears for suppuration, the teeth for abscesses, and the general musculature for evidence of paralysis.

In a well-developed contracture of the sterno-mastoid the only effective method of treatment is to relieve the contracture by cutting. The only question is where to cut—at the mastoid insertion, in the middle of the muscle, or at the tendinous clavicular end. Incision at mastoid, as done by Mikulicz, has the advantage of a concealed scar, but the disadvantages outweigh this. The insertion is rather extensive, and it is easy to miss some of the muscle fibers which may later cause a recurrence of the deformity. There is danger of injuring the spinal accessory nerve in this region. Myotomy in the middle of the muscle and lengthening by Z-shaped incision is done by some surgeons, but

here also the amount of tissue to be cut is large and hemorrhage is extensive. The internal jugular vein is more in danger here than elsewhere. Tenotomy near the clavicle is the method employed by most surgeons. Open incision about 3 cm. in length along the upper border of the clavicle, beginning at the proximal end and extending outward. The tendon is carefully separated from the underlying veins and cut on a dissector, which is passed under it. As soon as the tendon is cut, the head should be twisted into an overcorrected position. This immediately brings out any uncut fibers of the tendon or any other contracted tissues which can then be severed. Delrez cuts, not only the sternal and clavicular tendons, but the fascia clear back to the border of the trapezius. He does not immobilize, but allows free movement so that the deformity can correct itself. In severe cases it is advisable to resect one or two centimeters of the tendon and muscle, as insurance against recurrence. Schubert reports a case in which it was necessary to resect the entire muscle and the spinal accessory nerve to obtain a good result.

After operation the patient is more comfortable, and a better result is insured if the head is immediately immobilized in an overcorrected position. This may be done by applying a plaster cast while the patient is still under the anesthetic. Some surgeons wait until nausea and vomiting are over to avoid soiling the cast, but others have found that, on account of tenderness, it is difficult to get the patient's co-operation sufficiently to obtain at this time the extreme overcorrection necessary to insure a good result. The cast must come well down on the thorax, to furnish a firm anchorage for the head piece. In a method which I observed in Belgium during the war the cast included the shoulder and upper arm on the side opposite the tenotomy. An objection to this method is that with adduction of the arm the head tends to move back toward the original position of deformity.

In lieu of a cast there are several forms of harness-like appliances which hold the head in the proper position, provided the patient does not loosen the buckles.

Complications during or following the operation may occur. The jugular vein may be opened and serious hemorrhage result. Nerve injury may be caused by stretching of the upper spinal nerve roots while making the overcorrection. Engel reports a case of paralysis of the deltoid, biceps and supination longus, which was noticed on removal of the cast. It seemed to have been due to tension on the fifth and sixth roots, and gradually disappeared.

After immobilization for about four weeks, massage and motion is started. The chief aim of massage and passive motion is to prevent recurrence of the contracture and adhesion of the scar to the bone. Active exercises should include all the muscles around the neck and should begin early, to avoid protracted stiffness. Stimulation of the circulation by baking is a valuable aid in obtaining the softening of the tissues, which is necessary to free motion. If the patient is treated three times a week for a month, and observed once a week for two months thereafter, there will not be much chance for recurrence.

In children under about 3 years of age torticollis may be completely cured by physiotherapy without operation. The same may be said of very mild cases at any age. Treatment should be given daily, consisting of forcible stretching followed by exercises. Some form of retention apparatus may be worn to maintain as much correction as possible between treatments.

Cases on the border line, where it is doubtful whether operation ought to be done or those patients who refuse any cutting, may be given an anesthetic and the tight muscle forcibly but slowly stretched. A cast is then applied, maintaining as much overcorrection as possible. This procedure may be repeated as often as necessary, and is followed up by physiotherapy in the same manner as after open operation.

The results of operative treatment are very good. The younger the patient, the better will be the result. Complete correction and disappearance of facial asymmetry can be expected in children under 12. In patients over 20 the change in shape of the cervical vertebra secondary to the long-continued position of deformity may preclude a complete restoration of the normal position. The asymmetry of the face in such cases may not completely disappear. It is wise to consider carefully before undertaking operation in adults, since there may be obtained only enough correction to accentuate the crooked face and the patient will consider that he has been made worse instead of better.

810 Professional Building.

DISCUSSION

R. S. ZUMWALT, M. D. (960 Guerrero Street, San Francisco)—I have read Dr. Clark's very able paper, and congratulate him upon the thorough way in which he has covered the subject.

I was glad to notice the warning he gives regarding adult patients with facial asymmetry in addition to their torticollis, a very frequent combination.

JOHN C. WILSON, M. D. (1136 West Sixth Street, Los Angeles)—The subject of torticollis has been very thoroughly covered by Doctor Clark.

The question of etiology brings up some interesting discussions. The theory of interstitial myositis being the principal cause seems the most rational. A hemorrhagic myositis has been known to develop into an interstitial myositis with contractions even with massage, and it would seem that trauma during passage through the birth canal, with ensuing hemorrhage and fibrosis, must be regarded as the most probable cause. If such is the case the term "congenital torticollis" becomes a misnomer.

Correction as early as possible is always proper because of the danger of a cervical scoliosis, which is certain to develop during the period of growth if the deformity of the head is not corrected.

Serious accidents have been reported following the immediate application of plaster of paris dressing after operation, probably due to stretching of the vagus nerve. As a rule, the head can be held in position by sand-bags or adhesive plaster for two or three days, and a plaster dressing may then be applied in safety without lessening the correction.

If the condition has been of long duration, structural changes in the cervical spine become the most important factor in the treatment. Exercises, both active and passive, may be necessary for several months.

LIONEL D. PRINCE, M. D. (Flood Building, San Francisco)—Doctor Clark has given us a very excellent paper on torticollis. The etiology of congenital torticollis, in common with other congenital anomalies, has always been a source of controversy. While there is no doubt that the cause and pathology may be definitely determined in certain cases, the origin of cases which are either associated

with combined congenital anomalies or where heredity is in evidence has not as yet been explained. The pathology frequently seen, such as lessened contractibility of the involved muscles or a fibrous myositis, except in those cases where there is a history of trauma or infection, may be secondary changes resulting from the anomalous condition.

The facial asymmetry associated with a case of torticollis is purely static and simply another instance of accommodative anatomical changes to abnormal posture. If the one-sided position of the head is corrected during the developmental period the asymmetry will gradually disappear. One occasionally sees this same type of asymmetry in children where the head has been tilted over a period of a number of years, as a result of an acquired condition such as tuberculosis of the cervical spine.

The operation of choice is that best described by Clark, namely, a tenotomy at the lower end of the muscle. Subcutaneous tenotomy is dangerous and should never be employed. In most cases it is necessary to incise both the sternal and clavicular attachments of the muscle.

The maintenance of the overcorrected position in a plaster paris splint, following operation, is extremely essential. The application of the splint two or three days after the operation is preferable in those cases where the type or disposition of the patient will permit it. A precaution which I have found valuable, especially where the cast is to be applied immediately after the operation, is to have in writing, for reference, the desired position of overcorrection of the head.

W. C. S. KOEBIG, M. D. (1052 West Sixth Street, Los Angeles)—Doctor Clark has covered the subject of torticollis in a very thorough manner.

The etiology of torticollis offers a large field for discussion. There is much to be said in support of both those who hold the theory that it is congenital, and those who think that it is acquired. It would be reasonable to suppose, however, that the men who hold the theory that difficult delivery is a result rather than a cause of torticollis, owing to the abnormal relationship of the parts in the birth canal, have much to support them. There can be further injury to the muscles during birth. It would be interesting to note the number of cases of muscular torticollis there are following the Caesarean operation, and compare the percentage with that following delivery in the normal way. If the developmental theory holds true, then the percentage would not be diminished by Caesarean operation.

While the operation of choice is a tenotomy of the lower end of the muscle, in selected cases the operation in which the sternal branch is divided close to its insertion and the clavicular branch as high up as possible, followed by uniting the two cut ends, seems to be ideal. Convalescence is shorter and there is not so much formation of scar tissue.

The early maintenance of the head in overcorrection, held by plaster, is exceedingly dangerous, except in the very young, where the underlying tissues are pliable. The shortened blood-vessels, nerves, and other structures may be injured. Application of the plaster splint in as much correction as possible without using too much force, is preferable. In a day or so the cast can be split and more correction given. This can be followed every alternate day until the full amount of overcorrection is obtained. This method will give uniformly good results if judiciously carried out.

According to a Decision of the Judicial Council, A. M. A.—"By the term 'contract practice,' as applied to medicine, is meant the carrying out of an agreement between a physician or a group of physicians, as principals or agents, and a corporation, organization, or individual, to furnish partial or full medical services to a group or class of individuals for a definite sum or for a fixed rate per capita."

"Let everyone in every department of medical endeavor be forgetful of self, but mindful of the greatness and majesty of their calling, bend every energy toward the welfare of their patients. Let no diagnostic stone remain unturned to ascertain their trouble and no therapeutic measure neglected to insure their recovery."—*F. W. Mann, Ohio Med. Jour., Oct. 1, 1925.*

X-RAY DEEP THERAPY INSTALLATIONS IN CALIFORNIA

By W. EDWARD CHAMBERLAIN, M. D., and ROBERT R. NEWELL, M. D., San Francisco

On theoretical grounds the ionizing action of x-rays should afford the more useful measure of their intensity for biologic purposes.

An ion differs from a molecule by virtue of the electric charge it carries.

For about six months we have used the method of direct measurement of x-ray output and found that with the same setting, giving the same sphere gap voltage and with same milliamperes load, the x-ray output varied only a few per cent.

DISCUSSION by Frederick H. Rodenbaugh, San Francisco; John M. Rehfisch, San Francisco; Albert Soiland, Los Angeles; W. O. Weiskotten, San Diego.

IN THIS country x-ray dosages are usually recorded in milliamperes minutes, specifying the voltage, filter, distance, and area irradiated. But we have known for years that the same power input does not yield the same amount of x-ray on different machines, or with different tubes.¹

Various units have been advanced for specifying the x-ray intensity or total dosage at the patient's skin. Many of these depend upon relatively insensitive methods of measurement. The H unit (Holzknecht) depends on change of color in barium platino-cyanide, which is among the least sensitive. The X unit (Kienbock) depends on blackening of photographic paper, and is slightly more sensitive. The Furstenau intensimeter depends on changing conductivity of selenium and is sensitive, but is subject to theoretical and practical objections.

On theoretical grounds the ionizing action of x-rays should afford the most useful measure of their intensity for biologic purposes. Inasmuch as the x-rays which act are those which are absorbed, therefore the degree of ionization in an absorbing medium containing the same range of atomic weights as vital tissue should give a satisfactory measure of biologic dosage. The close correlation between biologic action and ionizing action in air has been demonstrated by several investigators.

An ion differs from a molecule by virtue of the electric charge it carries. Inasmuch as the charge is a definite quantity, one can use electrical units to measure numbers of ions. The unit usually chosen is e, the electrostatic unit of charge, which equals the charge on 2,100,000,000 monovalent ions. A unit of x-ray dosage has been derived from this and named E. It is that amount of x-ray (intensity x time) which will produce 2,100,000,000 ions in 1 cc. of dry air (under standard conditions of temperature and pressure).² It can be measured easily and accurately by measuring the one electrostatic unit of electricity that those 2,100,000,000 ions will ferry across an air gap. Such small quantities of

electricity are measured by an electrometer, an electroscope or a sensitive galvanometer. We have chosen the latter instrument as being the most easily calibrated and giving the fewest insulation difficulties. The one we used gives 2.5 mm. deflection for a current of 1 e per second. In order to get large deflections we used ionization chambers of large volume (210 cc.).

For about six months we have used this method of direct measurement of x-ray output and found that, with the same setting giving the same sphere gap voltage and with same milliamperes load, the x-ray output varied only a few per cent. Dr. J. M. Rehfisch of this city has had the same experience over a much longer period. The output of the two installations differed markedly. We get 1.3 E for each milliamperes minute with $\frac{1}{2}$ mm. of copper at 70 cm. He gets 2.1 E for each milliamperes minute with the same filter and phantom. This made it appear that x-ray dosage had better be recorded in E. This would be easy if we should determine for each laboratory exactly how many E per minute is delivered at its standard setting.

We, therefore, carried our ionization chamber imbedded in the surface of a large paraffin phantom and our galvanometer and calibrating instruments to the various deep therapy laboratories of California. We are supplying each laboratory with the actual x-ray intensity in E per minute produced at the surface of a standard phantom under a set of standard operating conditions. We have also compared their own filters. In order to apply these intensity determinations to ordinary operating conditions, it is only necessary to apply factors for distance, port-size and thickness of filter.

We have also compared the 10 cm. depth dose in paraffin for all the machines measured and find no significant variation. Paraffin was chosen for the phantom because of the necessity of its remaining constant during transportation. We plan to make comparisons between paraffin and water, and to transmit to each laboratory any important corrections.

Stanford University Hospital.

DISCUSSION

FREDERICK H. RODENBAUGH, M. D. (516 Sutter street, San Francisco)—The importance of Doctor Chamberlain's and Doctor Newell's measurements can hardly be estimated, particularly when it is the endeavor of this society to standardize, and compare the results of radio therapy of various laboratories throughout the state.

The greatest stumbling block to therapy has been the wide variability of methods of measurement. Each worker has biologically calibrated his own machine; a relatively inaccurate, and difficult procedure, and it has been very difficult to translate results from one installation to another.

The most important step in estimating the effects of radiant energy is to know the quantity required to produce a constant biologic response, if such a result is to be duplicated. Chamberlain and Newell, in calibrating our installations, have performed a very valuable service to roentgenology, and I am certain that their careful work will extend the usefulness of radio therapy.

JOHN M. REHFISCH, M. D. (St. Luke's Hospital, San Francisco)—This work of Chamberlain's and Newell's is extremely important. Aside from the invaluable data that they have given us in enabling us to transliterate terms of dosage with one machine into terms of dosage with another, it seems to me that they have made two

¹ The difference in x-ray output of different x-ray tubes has proven a very important factor in the case of the Universal Coolidge Tube, operated with moderately light filters or without filters. With the relatively high filtrations used in High Voltage Therapy, however, the differences become much less important. Using a filter of 0.05 mm. copper, we have found differences as great as 12 per cent.

² Corrections for humidity, temperature and barometer are negligible.

important contributions, contributions which I have been able to check and confirm in my own laboratory with different instruments and using a somewhat different technical method. First, they have exploded the honored fallacy that there is any difference in the x-ray output of different tubes under deep therapy conditions when a heavy metal filter is used. Variation from tube to tube is, in every sense of the word, negligible. Second, they have proved that, regardless of the fact that the various types of deep therapy machines in the market give very various x-ray intensities under equal conditions of milliamperage and filtration, the quality or penetrating power of their various beams is substantially, and for all practical purposes, the same. This is due to a fact that Chamberlain and Newell have not thought it worth while to bring out, but which I think should be mentioned, since it seems to be so generally ignored even among roentgenologists, and this is—that the penetrating power of all x-ray beams, under equal conditions of heavy metal filtration, is practically uniform, though their exciting voltage may vary anywhere from 120,000 to 250,000 volts. This, of course, is due to the much neglected fact that the overwhelmingly predominant constituent in the x-ray beams we use at and between and above these voltages is the characteristic radiation of the tungsten target. Although Milliken's law, that the minimal wave length varies constantly with the exciting voltage, is a scientific truth, it is not of any practical importance to radiotherapists on account of the fact that the small quota of gradually decreasing wave-lengths, produced by the gradually increasing voltage applied to the tube, is entirely overshadowed by the relatively enormous output of tungsten characteristic. A very useful article could be written upon the subject and I look to Chamberlain and Newell, to whom we are already so much indebted, to write it for us.

ALBERT SOILAND, M. D. (1407 South Hope street, Los Angeles)—One of the most important phases of x-ray therapy is the proper standardization of the dose. In the many complexes of radiation therapy, the measuring of the x-ray output can be accomplished if we avail ourselves of the lessons given in this valuable contribution by Doctors Chamberlain and Newell. We should all work to the end that will standardize our own instruments so that we can indicate intelligently to our colleagues the sum total of x-ray energy used in any given case. Our laboratory will be glad of an opportunity to co-operate with Chamberlain and Newell in this splendid work.

W. O. WEISKOTTEN, M. D. (First National Bank Building, San Diego)—For years it has been the aim of roentgenologists to develop a standardized technique for both diagnostic and therapeutic work in order that this technique may be the better described and duplicated as the occasion would demand. With the newer diagnostic apparatus and refinements in roentgen laboratory methods, it may be said that we are on our way toward more satisfactory end results. The aim of the diagnostic technician is to produce a perfect film from the diagnostic standpoint and be able to duplicate this film any time, regardless of the size of the patient, within reasonable limits. We feel that we have nearly approached that standard. But when the question of roentgen dosage is considered we have other problems and factors which enter into the proposition—the very problems so well described in this article. After all is said about x-ray dosage, it is the biologic effect that must be standardized and the method of measurement which produces the accurate biologic standard is the method to be employed. The older methods of dose measurement have their disadvantages and it seems to me that Doctors Chamberlain and Newell have the right idea. The solution of the problem lies in the standardizing of the output of each individual installation so that duplication of results may be obtained and accurate dose units may be described in literature for the benefit of others.

Health is not to be purchased by sloth and idleness; for those are chief inconveniences of sickness; and there is no difference between him who thinks to enjoy his health by idleness and quiet, and him who thinks to preserve his eyes by not using them, and his voice by not speaking. For such a man's health will not be any advantage to him in the performance of many things he is obliged to do as a man.—*Plutarch's Rules of Health.*

GASTRIC MOTOR DISTURBANCES AND THE VISUALIZATION OF THE APPENDIX

By R. C. SHAWHAN, M. D., *Los Angeles*
(From the X-ray Service, Veterans' Bureau Hospital
and National Military Homes for Disabled
Volunteer Soldiers)

THE stomach is the chief regulator of the rate of small intestine motility; the rate in the jejunum is very rapid, periodic and segmental; and the ileal motility lacks these characteristics. The rate decreases from the duodenum to the ileocecal valve. This valve has a dual function; to prevent a too rapid flow of intestinal contents and to prevent a reflux of cecal contents into the ileum. Any pathology which might disturb these factors will influence the intestinal motility.

In sthenic types the intestine is high; in asthenic it is low, the coils are less discrete, and demonstrate a less degree of tonus. There are modifications and degrees of conditions and habitus, but organic diseases make definite changes readily demonstrable in the x-ray film; for instance, obstructive carcinoma of the colon results in a proximal dilatation, reflexes diminished, motility lessened, stasis, defects in barium fillings, and reflex disturbances noticeable throughout the intestinal canal. While a duodenitis, colitis, or small ulcer cause a hypertonus, hypermotility, the meal passes so rapidly that the films are ill-defined or must be taken in rapid succession to give definite knowledge; right here the fluoroscope is our best friend. In fact, the day will soon come when the gastro-enterologist will enter the fluoroscopic rooms with the roentgenologist and see for himself. While a good film is the best argument for a statement, still a first-class demonstration with the fluoroscope will make many reports superfluous. The best time to ask questions and pick flaws is at the fluoroscopic seance, where any turn or movement has its peculiar movement visualized for only a moment, then it is lost forever.

The routine x-ray examination in most hospitals is to review the esophagus, see the meal enter the stomach, view the duodenal cap, take a few films, have the patient return in six hours; at this time the small intestinal canal is well filled and emptying. To see this filling, observations should be made more frequently and the passage of the barium observed. If the physician is present at the examination no films will be necessary, or, if taken as a matter of record, may be made at definite intervals.

There is a wide range of anatomical variation from the usually accepted normal in form, position, density, capacity, and patency which may not be inconsistent with perfect working ability. The same individual may operate his alimentary canal differently under different conditions. The roentgenologist must keep these various factors in mind, and only by constant vigilance, by repeating hundreds of similar examinations and constantly eliminating the ever present defects can he come to conclusions which are valuable in diagnosis. Probably we may get definite information of a more satisfactory character if we are privileged to ray the second generation. Some of our favorite diagnosis may turn out to be family characteristics if watched through these changes; or be the metamorphosis of evolution. Anatomical members which the surgeon is readily

eliminating from society may be the embryonic formation of a future useful organ. Let us make progress slowly, view with leisure freakish advances and reserve our opinions for a more sane expression of facts.

That the appendix does or does not fill is unimportant. What takes place after filling is of real moment. Like diverticulitis, which implies inflammation, diverticulosis means only a small inoffensive pouch. Emptying is far more potent, and still more significant are the effects in the alimentary canal.

Most appendices are discovered in routine gastrointestinal series work and are visualized without any special technique, although Knox says by special care from 80 to 90 per cent can be seen. I do not know of any means by which I can either cause the appendix to fill or keep it from filling. Barium enemas seldom fill the appendix, although they may cause an apparent incompetency of the ileocecal valve, which is in no other way pathological.

The gastric findings which are so frequently associated are vigorous peristalsis, hypertonus, pylorospasm, irregular hypermotility, defective duodenal cap, and duodenal ulcer, the absence of reversed peristalsis, pyloric adhesions, gall-stones, and frank organic lesions.

Visualized appendices are classified as follows: Angulated, kinked or coiled, beaded, broad, narrow, long, short, high, low, horizontal or vertical. The appendix may be well filled, yet so placed behind a well-filled cecum that it is not seen. Skinner states that the visualized appendix, after the age of 30, is pathological. Case says that he has seen barium retained for six months. I have seen the visualization at one examination and not a trace to be found in another in the same patient. Some appendices will fill and empty in a rhythmic manner quite as regular as the stomach. The fact that it fills or does not fill has little to do with determining the pathology. One may fill at 10 or 50 years of age; it may empty in twenty-four hours or may retain the barium for months and not be pathological. What really takes place in the appendix determines the pathology; and a diseased organ will also cause gastric and intestinal disturbances registered on the x-ray film and in the fluoroscope.

Visualized appendices with hypertonic stomach, vigorous deep peristalsis, irregular motility, pylorospasms, cecal stasis, duodenal ulcer, and adhesions in the right iliac fossa, can safely be classified as x-ray evidence of chronic appendicitis or the determining etiological factors of acute appendicitis.

I do not like the term laboratory diagnosis or x-ray diagnosis. Let us simply report our findings. We are all physicians collaborating our specialties for the benefit of mankind. My enthusiasm may cause me to see more and place more importance on small matters; your broader practice may cause you to consider bigger things; the patient's anxieties and his responsibilities to his family may determine his decisions—but each of us when we seem cocksure may stand aghast at the autopsy findings.

Take the reports of any specialist and trim them of their technicalities, their fads and their fancies, clear away the chaff. You may not have much left, but it will serve a genuine purpose and may be the one strong link in the chain of diagnosis.

X-RAY DIAGNOSIS OF KIDNEY TUMORS

By MARK BROWN, M. D., Ogden, Utah
(From the Department of Roentgenology, Dee Hospital)

Radiography a very important aid in the diagnosis of kidney tumors.

DISCUSSION by George Lee Eaton, San Francisco, and Lloyd Bryan, San Francisco.

IS IT necessary to make pyelograms in order to diagnose kidney tumors? We find that by using a fine focus tube and a low spark gap we are able to outline the normal kidneys in a patient up to 175 pounds. We also have found that in patients less than 180 pounds the kidney outlines are more distinct without a Bucky diaphragm. This is because soft tissue shows more distinctly when a three-inch gap is used than when a five-inch gap is used, as is necessary with a Bucky diaphragm.

If the kidney tumor is on the right side and a differential diagnosis from enlarged gall-bladder is desired, it is necessary to make an exposure with the patient on his abdomen. If the outline of the shadow is smaller and clearer when the patient is on his back than on his abdomen, the tumor is nearer the back and closer to the plate, and hence is probably a kidney shadow.

In four recent patients, radiographs showed abnormally shaped kidney shadows in which a diagnosis of kidney tumor was made. In three of these, operation confirmed the diagnosis, while in the fourth, autopsy revealed a kidney tumor.

CASE RECORDS

CASE 1—Male, 35. Complaint, hematuria. He had three attacks within one year, each attack lasting two days. No pain and no other symptom and no tumor palpable. He had been cystoscoped three times previously and the source of hemorrhage was not ascertained.

Roentgenograms showed a normal shadow of the right kidney. The left was enlarged and irregular as shown in Figure 1. The cystoscopic examination showed a normal bladder and ureteral orifice. The urine from the left ureter was blood stained. The patient would not consent to an operation until he had had two subsequent attacks and began to have a dull constant pain in the kidney region. Operation revealed a kidney tumor the size and shape of the x-ray shadow. The pathological diagnosis was hypernephroma.

CASE 2—Female, 28. Complaint, pain and a mass in the upper left abdominal quadrant. There was no haematuria or loss of weight. A barium meal and enema showed the mass to be behind the peritoneum. Functional kidney test revealed no phenol-sulphon-phthalein from the left ureter.

X-ray of the kidney region showed a normal right kidney. The left was enlarged, the lower border reaching two inches below the iliac crest. An operation showed a large kidney tumor adherent to the surrounding structures. As it was impossible to remove the tumor the incision was closed. At autopsy the kidney was removed and found to be the same size and shape as the x-ray shadow. Pathological diagnosis: hypernephroma.

CASE 3—Male, 30, weight 180. Complaint, haematuria, but no pain and no palpable mass. Patient had previously been cystoscoped and a diagnosis of papilloma made. Cystoscopic examination at this time revealed the bladder area near the left ureter covered with numerous papilloma.

X-ray showed the right kidney shadow normal. The left was enlarged and irregular. This patient refused operation and lived eight months. An autopsy showed the kidney tumor to be a hypernephroma.

CASE 4—Male, 24. Had gonorrhea two months ago. He

was treated up to two weeks ago with deep instillation of mercurochrome. Two weeks ago he developed fever and pain in the abdomen over the gall-bladder region. One week later a tumor appeared in the upper right quadrant of the abdomen. There was only slight tenderness in the front and none in the back over the kidney.

Five physicians examined this patient, and, because there were no kidney symptoms except a small amount of pus in the urine, which was probably due to the chronic gonorrhea, kidney trouble was ruled out. As the tumor was apparently just under the abdominal wall, a pronounced diagnosis of abdominal tumor was made and the patient referred to the radiologist for examination

and report. The radiological diagnosis of enlarged right kidney caused some surprise to the surgeons. An abdominal incision was first made, but was immediately closed. Incision from the back exposed a very large pus kidney which was removed.

My technique for kidneys is 20 milli-amperes, 20-inch distance with compression, 10 seconds exposure, and only $2\frac{1}{2}$ to 3-inch spark gap.

DISCUSSION

GEORGE LEE EATON, M. D. (Medical Building, San Francisco)—It is a most important question to decide which technique to use when we are confronted with some remote kidney lesions. Roentgenologists are making improvements, and new apparatus to further aid this speciality, as they recognize that perfect kidney pictures that will show distinct lesions of the same are rare.

I am a great believer in the art of x-ray, with radiographic catheter, which, when placed in the kidney pelvis, will answer a two-fold purpose—first the collection of urine and general position of the kidneys, and second, the course of the ureter. With such a plate made upon the Bucky diaphragm, all foreign shadows may be eliminated if not in the ureter or kidney. A second plate follows with each kidney pyelogram and should show any pathological contours of the kidneys, or abnormalities of the calices.

LLOYD BRYAN, M. D. (135 Stockton street, San Francisco)—Doctor Brown is right when he says that it is not always necessary to make pyelograms in order to diagnose kidney tumors. However, I feel that, in the majority of cases, pyelograms, in addition to plain films, would be a much safer procedure. A large kidney shadow, of course, does not always mean a tumor of the kidney. Occasionally congenital lesion, resulting in a

large kidney with a double pelvis, will give a large shadow. Also simple compensatory hypertrophy of one kidney, in cases where the opposite kidney has been disabled by a diseased process, such as tuberculosis, a large pus kidney, hydronephrosis, and occasionally large tuberculous kidneys will also cast large shadows. While in the plain film, the shadow cast by these several conditions may be exactly similar, the picture with a pyelogram will usually help to differentiate between these several conditions. In some instances, with extreme enlargement of the kidney, a definite kidney shadow is difficult to determine. In these cases usually the normal shadow of the psoas muscle is obliterated, and we have found that this has been a definite help in helping to diagnose lesions of the kidney.

SUPRASYMPHYSEAL CERVICAL CAESAREAN SECTION

WITH REPORT OF FOURTEEN CASES

By JOHN VRUWINK, M. D., *Los Angeles*

When dystochia presents itself late in labor and the management of labor has been relatively aseptic, suprasymphyseal cervical Caesarean section will give good results.

It should be forcibly emphasized that the operation has distinct limitations and frankly infected patients are better managed by Porro operation or craniotomy.

DISCUSSION by E. M. Lazard, *Los Angeles*; L. A. Emge, *San Francisco*; J. Morris Slemons, *Los Angeles*.

CLASSICAL Caesarean section offers an easy method of delivery. The relatively simple technic and immediate good results are not, however, always balanced by a smooth convalescence and an absence of complications. The end-result is necessarily of much greater importance than that labor be terminated at a time of distress. A smooth convalescence is dependent, to the largest extent, upon obstetrical judgment displayed in choosing the time for abdominal delivery. Low mortality and morbidity has again and again been demonstrated to be directly proportionate to the time of election for Caesarean section. Consequently, indications and contra-indications will always be the most important factors controlling the success of this method of delivery.

When the time of election for a patient in good general condition is at or near term, or shortly after the onset of labor, with intact membranes and no vaginal manipulations, complications following classical section will continue to be rare. The prognosis of such a patient is that of the ordinary uncomplicated laparotomy. In general, however, such indications too frequently are not discovered until labor has advanced beyond this opportune time. Then the more difficult methods of delivery, through the natural passages, must be considered and obstetrical judgment is never of greater importance. It is hardly necessary to comment on the fact that a Caesarean section is frequently chosen in lieu of formidable operations from below. The end-results of classical section at this time are not always unfavorable, but given the conditions that obtain after twelve hours of real labor, with several vaginal examinations and manipulations of sorts, especially in the presence of ruptured membranes, the maternal prognosis becomes dubious.

Delivery from below, in the presence of dystochia, is always of serious consequence to the mother and

baby. There is a real danger in Caesarean section when conditions are not favorable, but this same danger is not entirely eliminated by vaginal delivery. High forceps, forceps on the unengaged head, is of such serious consequence that it is but rarely attempted by the obstetrician today. Version and extraction, late in labor, when the lower uterine segment is thin, is a favorable condition for rupture of the uterus. Even craniotomy and decapitation in neglected cases have a serious morbidity and mortality.

Late in labor there may be an indication for delivery, but the conditions are neither favorable for a classical section, nor are conditions right for delivery from below. In any type of vaginal delivery, the degree of effacement and dilation of the cervix is of the greatest importance. Under such conditions the delivery of a live child is worthy of commendation, but too frequently such a termination is effected at a frightful cost to the mother. There is not only a definite mortality, but practically all the patients who survive are infected and so traumatized that plastic surgery is eventually required.

The real danger of classical section late in labor is sepsis. It has been proven many times that morbidity and mortality depend directly on the duration of labor, the number of vaginal examinations and hours that the membranes have been ruptured. After classical section, peritonitis is imminent in potentially infected cases whether the uterus is closed in one, two, three, or four layers; whether the abdominal incision is entirely above or below or partly above or partly below the umbilicus; whether the uterine and abdominal incision is closed with silk-worm gut, silk, linen or catgut, interrupted or continuous suture. The danger of sepsis is real, and since we know lochia can pass between the stitches into the peritoneal cavity, it is reasonable to believe that bacteria can pass from the uterine cavity into the peritoneal cavity.

The active etiological factor of a spreading peritonitis after uterine incision is in the uterus after suture and sepsis results from the ability of the bacteria to find their way into the peritoneal cavity. Shock and traumatism of the gut are important predisposing causes, but to prevent sepsis means safeguarding the contents inside the uterus, either by operating before infection gains entrance or by removal of the uterus after infection; or by peritonizing the uterine incision so that infection remains extraperitoneal. Most authorities believe that the spill is of little serious consequence.

Surgeons long ago recognized this danger and careful peritonization is meticulously carried out after removal of the appendix, and after hysterectomy in the care of the cervix. Obstetricians have long recognized the danger attending classical Caesarean section late in labor, and efforts were made early to perfect a technic whereby the child could be removed without exposing the peritoneal cavity to infection. In 1807, Jorg first suggested a true extraperitoneal delivery. The modification of the low cervical section advocated by Beck of Brooklyn and De Lee of Chicago is not a new operation. There have been twenty or more variations of the original operation. The technic simultaneously evolved by them does, however, more nearly approach the aim

of clean surgery, in that the incision is peritonized in such manner that infection, when present, is confined outside the peritoneal cavity.

The technic is much more difficult than that of the classical section but not a valid contra-indication to its use, and the surgeon accustomed to abdominal surgery should find no difficulty in its execution. The skin incision may be either through the midline or a Pfannenstiel incision. The longitudinal incision begins at the pubis and extends 14 centimeters toward the umbilicus. The muscle is divided to the right of the incision, the fascia and peritoneum opened as in the ordinary laparotomy. Such an incision exposes the thinned-out lower uterine segment. The intestines are not visible. A pack is not necessary.

The visceral peritoneum is incised transversely in the midline at a point about 2 centimeters above the bladder and extended to right and left in a curvilinear incision. The visceral peritoneum is stripped from the uterus above and with the bladder separated below. In this manner, exposure is obtained of an area in the lower uterine segment through which to extract the child. The uterus is then incised longitudinally and the child extracted. The extraction is carried out by the operator placing his finger in the baby's mouth and rotating the face into the incision. The forceps, with the cephalic curve to the occiput, are then applied. The liquor amnii and blood is advantageously removed by suction. Allis' forceps or catgut sutures at the upper and lower end of the incision, inserted before the uterine incision, aid in placing sutures. A No. 2 chronic twenty-day catgut suture is either used as a continuous suture with closure in two layers or interrupted sutures are used. Care is exercised in placing the suture down to, but not through, the mucosa.

De Lee has demonstrated a facial layer between the peritoneum and uterine muscle, and this is then closed with a continuous suture. The upper flap of peritoneum is then carried down over the upper two-thirds of the incision and tacked with plain gut-interrupted sutures. The lower flap with the bladder is then carried over the upper flap and sutured with a continuous stitch. The incision in the uterus is thus peritonized and within a few hours a barrier is raised which prohibits a ready access of the uterine contents from gaining entrance through and between the stitches into the peritoneal cavity. Bleeding is not severe if separation of the peritoneum is carried along the lines of cleavage and the uterine incision is in the midline.

It is not necessary to give pituitary extract or ergot because incision is in the non-contractile lower uterine segment. After the baby has been extracted, pituitary extract may be given to hasten separation of the after-birth and to control bleeding from the placental side. Manual removal may be required for the placenta, though it is better to allow separation to occur spontaneously and deliver between the stitches.

There is obviously a distinct advantage in the low cervical section, provided it will do what has been claimed for it by Beck and De Lee. Newell is of the opinion that no operation which conserves the uterus offers a good chance of preventing peritonitis because bacteria may find their way through the un-

opened peritoneum. In the German clinics, the operation has been carried out on patients with a fever with good results. Beck, in his first article, reports a personal series of thirty-seven cases with one death, probably due to eclampsia. He reported later a series of eighty-seven sections by various operators with three deaths, one due to septicemia, hemolytic streptococci were found in the blood on the fifth day; one from peritonitis, probably due to transmission of infection through lymphatics; and one from postpartum hemorrhage two hours after delivery in a patient with an atonic uterus after prolonged labor. An incidence of mortality from sepsis of 2.8 per cent in seventy-one potentially infected cases. Fifty-one patients had been in labor five hours or more. Membranes were ruptured in fifty-three, and more than ten hours in thirty-three cases. There were only twenty-five of seventy-four patients who had not been examined vaginally before operation.

In a personal communication from the Chicago Lying-in Hospital, Doctor Cornell states that there have been 256 of these operations, with one maternal death. This occurred in a primipara aged 45, weighing 278 pounds. She had been in labor four days with ruptured membranes forty-eight hours or more and had a blood pressure of 208/160, with marked albuminuria and edema. Not all of the 256 patients were operated on by members of the staff. Doctor Pierce writes that sixty operations have been done under local anesthesia.

Phaneuf reports five cases with no complications. He reserves the Beck operations for clean cases and the Hirst operation for doubtful cases.

Welton reports eleven cases, seven with potential infection at time of operation. There was no peritonitis and maternal mortality was nil.

Hirst and Van Dolsen report 107 cases done by the low cervical route. All were advanced in labor, in a condition unfavorable for classical operation. Two died, one due to mesenteric embolism and one from acute dilation of the heart, due to chronic myocarditis eighteen days after operation. There were no cases of peritonitis.

John A. McGlinn of Philadelphia says that after twenty years of experience he holds the so-called newer operations with a certain degree of skepticism and, in conclusion, says: "The operation is over a century old. There has hardly been a new thought advanced, pro or con, except variations in technic. The operation has never been generally accepted and it never will be. While it has many advantages, they are overshadowed by its disadvantages. It is a laudable object to perfect technic to reduce mortality, but our real problem is to raise the standard of obstetric knowledge and practice as to make the operation unnecessary."

There should be no necessity for this type of operation, an operation designed to meet an emergency when potential infection has occurred. All patients, when unexpected dystochia arises, should have been operated by section just before or shortly after the onset of labor. For a century there has been a demand for an improved technic. For a century there has been a need for some method of terminating labor; to obviate the bad results late in labor of classical section, and the operative measures necessary from below. Even patients with adequate

prenatal care and during labor may arrive at the point where delivery from below is dangerous and classical section contra-indicated.

At the Los Angeles General Hospital we have been ultra-conservative in advising the low cervical section. There were only eleven cases in the past year, not a great number, and yet each section but one was performed on a patient potentially infected and for that reason of importance. Sections were done on the service of L. G. McNeile and Lazard, by Farrel, Irwin, and Vruwink.

197262. Mexican, age 19, para 1. Wassermann negative; labor 46 hours or more; dilatation of cervix 3 cm.; B. O. W. ruptured 46 hours or more; vaginal examination after rupture of B. O. W., three or more by midwife; O. L. A. head above inlet; generally contracted pelvis. Suprasymphyseal Caesarean section Nov. 9, 1923. Puerperium afebrile and uneventful.

197725. White, age 18, para 1. Wassermann negative; labor 36 hours; dilatation of cervix 2 cm.; B. O. W. ruptured 8 hours or more; vaginal examination—several at home before and after rupture of B. O. W.; 2 in hospital; O. L. A. head above inlet; suprasymphyseal Caesarean section Oct. 23, 1923. Puerperium febrile 102.6 twelve days; 101 four days; 100.6 six days; considerable drainage throughout lower angle of incision; post-operative course uncomfortable because of gas pains.

198642. Mexican, age 34, para 1. Wassermann negative; labor 48 hours or more; dilatation 2 cm.; B. O. W. ruptured ten hours; had "private doctor" first 12 hours; number of vaginal examinations not known. Advised by City Maternity Service to go to hospital after 12 hours of labor; refused; one vaginal examination in hospital. O. D. P. head above inlet; generally contracted and flat pelvis; suprasymphyseal Caesarean section Nov. 9, 1923; puerperium febrile 101.4 fifteen days; 101.8 twelve days; 103.4 one day; 102.4 two days; temperature dropped when drainage through lower angle of incision became established; post-operative course uncomfortable because of gas pains; left hospital well on thirtieth day.

199811. Mexican, age 19, para 4. Wassermann suspicious. Classical Caesarian four years ago with first pregnancy; second and third pregnancies terminated spontaneously; labor 64 hours; no dilatation. B. O. W. intact; two, probably more, vaginal examinations before entering hospital; transverse presentation; thin lower uterine segment; suprasymphyseal Caesarean section Dec. 2, 1923. Puerperium afebrile and uneventful.

214187. Colored, 19, para 1. Wassermann negative. Labor 48 hours or more; threatened rupture of uterus; dilatation of cervix (?); B. O. W. intact; no vaginal examinations; O. D. P. head above inlet; rachitic flat pelvis; suprasymphyseal Caesarean section Aug. 20, 1924; pulse 115, temperature 100; puerperium febrile; 101 three days; 100.4 two days; drainage from lower angle of incision profuse; post-operative course comfortable; left hospital after 32 days.

207885. White, age 35, para 1. Wassermann negative; labor 4 hours. B. O. W. ruptured 4 hours; no vaginal examination; O. D. P. funnel pelvis; suprasymphyseal Caesarean section May 6, 1924. Puerperium afebrile and uneventful.

214887. Mexican, age 34, para 1. Wassermann negative; labor 72 hours; dilatation of cervix 4 cm.; B. O. W. ruptured 96 hours; two vaginal examinations in hospital; O. L. A. head above inlet; mild toxemia; large baby (10 lbs, 4 ounces); suprasymphyseal Caesarean section August 5, 1924. Pulse 84, temperature 102.2. Puerperium febrile 101 one day; 102 one day; 100.2 four days; drainage from lower angle of wound; post-operative course comfortable; left hospital twenty-second day.

215948. Mexican, age 17, para 1. Wassermann negative; labor 51½ hours; B. O. W. intact; midwife for 2 days; vaginal examinations 3-5(?); O. L. A. head not engaged. Systolic murmur and thrill; systolic 140, diastolic 100; edema; urine negative; suprasymphyseal Caesarean Sept. 28, 1924; pulse 96; temperature 94.2. Puerperium febrile, patient died eleventh day post-opera-

tive. Partial autopsy showed the peritoneal reflections intact with no spreading peritonitis. No exudate covered the intestines. Free pus in pelvis which undertaker said followed trocar in uterus. Death evidently due to generalized infection. Porro section would probably have saved this patient. It emphasizes forcibly the advisability of aseptic management of labor and the urgent necessity of hysterectomy in frankly infected patients, especially in the presence of toxemia and exhaustion.

Pathologist's report, G. D. Maner: "Specimen consists of a small piece of uterine muscle. On cross section are seen several thrombosed vessels. Microscopical examination shows the blood vessels filled with septic thrombi. Along the external portion and including serosa there is a very acute cellular inflammatory reaction. The myometrium throughout its whole extent is diffusely infiltrated with polymorphonuclear leucocytes and extravasated red blood cells. Muscle cells are hypertrophied and nuclei show degenerative changes."

215977. Mexican, age 32, para 1. Wassermann negative; labor 48 hours or more; dilatation 4 cm.; B. O. W. ruptured 21 hours; vaginal examinations none; O. D. P. head not engaged; contracted pelvis threatened rupture of uterus; suprasymphyseal cervical Caesarean section Sept. 27, 1924; puerperium afebrile and uneventful.

217210. Colored, para 1. Wassermann negative; labor 79 hours; dilatation 2 cm.; B. O. W. ruptured 76 hours; number of vaginal examinations at home not known; none in hospital; O. L. A. contracted pelvis; suprasymphyseal cervical Caesarean section Oct. 13, 1924. Puerperium febrile 102, one day; 102.8 one day; 103 one day; 101.4 two days; course comfortable; left seventeenth day.

217712. Age 18, para 1. Wassermann negative; labor 34 hours; dilatation 4 cm.; B. O. W. ruptured 9 hours; 3 vaginal examinations in hospital; brow presentation; suprasymphyseal cervical Caesarean section Nov. 1, 1924. Puerperium afebrile and comfortable.

I can add three cases from private practice:

Mrs. G.; para 1, age 33. Labor 24 hours; dilatation 3 cm.; O. L. A. head above inlet; no vaginal examinations; B. O. W. intact; suprasymphyseal cervical Caesarean section Jan. 20, 1924. Puerperium comfortable and uneventful except for stitch abscess.

Mrs. A.; consultation; para 1, age 30. Labor 16 hours; dilatation 3 cm.; B. O. W. ruptured 5 hours; kyphosis with spinal deformity too low to permit of sufficient compensatory lordosis. Suprasymphyseal cervical Caesarean section Aug. 21, 1924. Puerperium uncomfortable because of gas pains. Highest temperature 103; stitch abscess; left hospital after two weeks.

Mrs. J.; consultation; para 1, age 33. Labor 36 hours; dilatation 3 cm.; chin posterior not engaged; no vaginal examination; B. O. W. ruptured 24 hours or more; uterine segment thin; suprasymphyseal Caesarean section by L. G. McNeile, Oct. 22, 24, 1924. Puerperium afebrile and comfortable.

There are advantages and disadvantages to the low cervical section. The disadvantages are:

1. The factor of time and greater technical difficulty. It is true skill should not be acquired at the price of the life of the patient, but neither should the patient be sacrificed by doing a classical section when infection is inevitable, or by doing mutilating operations from below which give a high foetal mortality and at best a maternal morbidity with invalidism.

2. Danger to the bladder and uterus. Abdominal operators are not deterred from hysterectomy when indicated because of this danger. Why should it be a contra-indication for a low cervical section? A retro-peritoneal abscess is much more likely to spread through soft tissue than through the resistant bladder wall.

3. The very frankly infected cases should be de-

livered by section followed by a hysterectomy or by a craniotomy.

The advantages are:

1. A real test of labor is possible. Guesswork and unnecessary sections are eliminated. A very evident advantage.

2. The incision is in the non-contractile portion of the uterus and in the cervix, which stands infection better than the fundus and is unaffected by uterine contractions.

3. The healing of the cervix is better than that of the fundus because active involution and fatty degeneration of the uterine wall defeat the healing power of the tissues (Monroe Kerr).

4. Better coaption, less danger from leakage. Sutures in the cervix can be perfectly coapted and covered with both fascia and peritoneum. Sutures in the fundus must be tight, in strong contractile muscle, and therefore subject tissues to necrosis. If leakage does occur, it is extraperitoneal and consequently less dangerous and more easily handled.

5. Adhesions and subsequent intestinal obstructions are reduced to a minimum. The uterine incision is peritonized by a double flap of peritoneum. The intestines and omentum are not usually in view during operation.

6. Convalescence is easier, there is less shock, as the intestines are not handled; post-operative vomiting and tympany are markedly reduced.

CONCLUSION

There should be no need of an operation to reduce maternal mortality due to sepsis or exhaustion, shock and sepsis with dystochia in labor. Better prenatal care, with classical section at or before labor gives favorable results. When dystochia presents itself late in labor and the management of labor has been relatively aseptic, suprasymphyseal cervical Caesarean section will give much better results. It should be forcibly emphasized that the operation has distinct limitations, and frankly infected patients are better managed by Porro operation or craniotomy. However, the obvious advantages in relatively clean cases may even make it the section of choice.

1021 Pacific Mutual Building.

DISCUSSION

E. M. LAZARD, M. D. (2007 Wilshire Boulevard, Los Angeles)—Doctor Vruwink's paper on the low cervical Caesarean section brings before us an operation which, in the past few years, has been popularized by Beck and De Lee. So much has been said of its safety in *potentially* infected cases that I fear the impression has become prevalent in the profession that this operation is a panacea for all neglected cases. That it does not remove the danger is proven by the report of Beck quoted by Vruwink, in which there was a mortality from sepsis of 2.8 per cent of seventy-one cases; and of the one death from sepsis in Vruwink's series. While the doctor concludes that this was a frankly infected case, and should have had a Porro, yet she had a pulse of 96 and a temperature of 99.2 before operation, and after 51½ hours labor.

In the early years of my work at the Los Angeles General Hospital nearly all of my sections were on patients who had been in labor many hours, all had had one or more vaginal examinations and several had had operative attempts from below. Yet my first seventeen cases were without mortality and with only a moderate

morbidity. After doing a classical section on a patient upon whom a forceps attempt at home had been persisted in for three hours, and having a convalescence disturbed only by slight stitch infection of the abdominal wall, I began to think my technic was infection proof. The next patient, one who was apparently in better condition than the one first cited, was my Waterloo. She was dead of sepsis within 30 hours after operation.

So I believe that while any attempt to improve our technic with the idea of reducing mortality and morbidity is most commendable, yet, I believe, we should use the utmost care in the selection of cases. Personally, I believe that where there is any serious question as to the possibility of infection, and where abdominal delivery is to be done, the best interests of the patient would be conserved by a Porro operation. The low cervical section, I believe, will be indicated in those cases which have been given the thorough test of labor under competent supervision and where the possibility of infection is reduced to a minimum.

L. A. EMGE, M. D. (350 Post Street, San Francisco)—Doctor Vruwink is to be congratulated on the conservative stand he has taken in regard to the so-called low Caesarean section. Euthusiasm has very often destroyed the good that has come from an otherwise commendable but limited operation. The first low Caesarean section performed in the service of the Stanford Women's Clinic, on a patient potentially infected, ended fatally from embolism. The operator, to this day, is definitely prejudiced against this operation. Personally, I believe that the low section has a definite field, although I speak from only a limited experience. By all means should it be done in the potentially infected patient, provided that circumstances do not demand a Porro operation. As an operation of selection with a primary indication its usefulness should be limited to those patients in whom the head rides unusually high over the symphysis, because here the lower uterine segment has been greatly stretched out and the head delivers itself almost spontaneously after uterine incision. At all other times the operation carries a certain amount of danger from embolism if it is used within ten days before the onset of labor because the lower uterine segment has not yet retracted and the vesico-uterine plexus of veins will have to be disturbed in the preparation of the field to be incised. There is no question that operative skill constitutes a most important factor in this operation. Therefore, it should be undertaken only by those who are thoroughly conversant with the aspects of pelvic operations in general.

There is one great advantage of the low Caesarean section over the classical type in all cases considered, and that is the prevention of adhesions between the upper angle of the uterine incision and the lower angle of the abdominal incision. In spite of the most careful peritoneal toilet and in the absence of fever, such adhesions will prove quite troublesome to the patient.

I believe that the usefulness of the low Caesarean section is definitely established, that its application has a definitely limited field and that it should not entirely replace the classical section.

J. MORRIS SLEMONS, M. D. (Pacific Mutual Building, Los Angeles)—The report of Doctor Vruwink has, for me, more than usual interest because my prejudice against the operation he describes has been great enough thus far to deter me in giving it a trial. Like Vruwink, I have felt that nothing less radical than hyperectomy was desirable in frankly infected cases. And, at the other extreme, a less complicated operation in my experience meets satisfactorily the requirements when Caesarean section is performed on clean cases. This attitude narrows the usefulness of the operation described by Vruwink to cases where there is reason to suspect infection, though positive proof of its existence is wanting. In such cases, naturally, the treatment will vary according to prevailing conditions and I can imagine circumstances that might make preferable the operation in question. Nevertheless, to speak of the procedure as an extraperitoneal operation is misleading. The protection of the peritoneal cavity, to my mind, should be credited to the low incision in the abdominal wall. This site, I believe, is now widely utilized where the so-called classical Caesarean is performed.

After Caesarean section, as after all abdominal operations, the convalescence becomes more comfortable and smooth if not only food, but also water is withheld for forty-eight hours and the administration of the initial cathartic is further delayed until the next day. The benefits of this plan include less nausea, less distension and less pain; probably, this regime also acts favorably toward the limitation of local peritonitis, which active intestinal peristalsis would tend to make general.

The test of labor should not often be required if cases are constantly supervised and studied. The day of "procrastination obstetrics" is passing; we are becoming more and more competent to reach clear-cut decisions before the settlement of the question of the mode of delivery becomes imperative.

The omission of the fetal statistics in Vruwink's paper, I regret, for the welfare of the child is paramount when Caesarean section is performed, and thus becomes a fundamental factor in estimating the satisfactory character of the technique employed.

TREATMENT OF MORBID FEAR

By SAMUEL D. INGHAM, M. D., Los Angeles

It matters little whether the sense of fear excites the physical reactions, or the physical reactions precede the sense of fear. It matters much more that fear inhibits the vegetative activities and tends to rapid physical exhaustion.

Fear, like pain, is a necessary evil, and, generally, serves a useful purpose.

When a danger is unsuccessfully met and misfortune results, caution (or fear) is increased to meet the next similar situation.

It is important to remember the fact that many morbid fears arise from misconceptions, and correcting the misconception may remove the fear.

A morbid fear might be defined as a fear which, considered in its entirety, is useless or unfavorable to the individual manifesting it.

Every physician is dealing constantly with morbid fear reactions manifested by his patients.

There is a close analogy between the mechanism of morbid fears and the state of allergy or tissue sensitization caused by an overdose of foreign proteid.

The first requirement in the treatment of morbid fear is a careful analysis, qualitative and quantitative, of the emotional elements of the individual problem.

The patient should be placed in an environment sufficiently protected to meet his particular needs, avoiding, as far as possible, conditions which react on him as harmful stimuli.

Education of the patient in the principles involved and in the true status of his own problem is often of great value, although it is not possible to put it to practice in all instances.

It is desired to call attention particularly to the principles of sensitization and desensitization. Morbid fear is not cured so long as special protection is necessary and a permanent protected environment is undesirable.

When the patient has sufficient moral and physical stamina, he will attain control of the situation, although the psychic trauma may leave a more or less painful scar.

DISCUSSION by Nathaniel H. Brush, Santa Barbara; Thomas J. Orbison, Los Angeles; Charles G. Stivers, Los Angeles.

THIS paper is presented, not with the thought of contributing a new theory or method, but to appeal for a more careful analysis and evaluation of the fear reactions which are a part of almost every clinical problem, and to make some suggestions for their treatment.

We are not as much concerned with the merits of the James-Lange theory of the emotions as we are with their physiologic aspects. It matters little

whether the sense of fear excites the physical reactions, or the physical reactions precede the sense of fear. It matters much that fear inhibits the vegetative activities and tends to rapid physical exhaustion. The extent to which these reactions affect the general health may be extreme. During the recent war, fatalities from acute fear were not uncommon, and in civil practice they are not unknown. Emotions are not only psychologic processes, but each has its characteristic general physical reaction. Overdetermined, any one may cause trouble.

We hear much regarding the effect of fear, not only as a prolific factor in the production of the neuroses, but as a disturbing process affecting the human race in an entirely unfavorable manner. Fear, like pain, is generally regarded as being undesirable, unwholesome, and altogether unnecessary. Not only is suffering caused by its presence, but it is a humiliation to confess it. In an article recently published in one of the best lay magazines, written by a university teacher in neuro-biology, the destructive effects of fear were emphasized in regard to individual, national, and international relationships. No intimation appeared in that article that the fear instinct might be a benefit to the individual or to the race. It is apparent that this view is entirely too narrow. Fear, like pain, is a necessary evil, and generally serves a useful purpose. It is pain which saves our fingers from destruction, makes possible the early diagnosis of appendicitis, and serves countless times in the life of every individual, saving life and tissue by a timely warning. So with fear: generally discredited and never eulogized, it acts as a tireless sentinel, constantly alert for danger, ready to give the warning signal and mobilize the forces of defense. It is on duty, not only during the waking period, but it serves also during sleep, as exemplified by the anxious mother who wakes instantly at the least sound of distress from her sick child. A recognition of the biologic value of the fear instinct is necessary in a consideration of its harmful tendencies, in order that we may determine at what point the reaction may be considered to be a harmful one.

CONSIDERATION OF THE PSYCHOLOGY OF FEAR

Fear is one of the most primitive instincts, and is manifested by important reactions in both the psychic and the physical field. It is excited by danger, real or fancied, and is often conditioned by a sense of inadequacy. It is concerned not only with immediate dangers, but with those far in the future, and some of the most painful fears are those excited by the dangers beyond the grave.

In every-day life dangers surround us in many forms. When successfully coped with, these dangers give a certain zest or pleasurable excitement to the experiences, and so self-confidence or courage increases. In this normal adjustment, fear in the form of caution maintains an alertness through the senses for the recognition of the signs of danger. When a danger is unsuccessfully met and misfortune results, caution (or fear) is increased to meet the next similar situation. Repeated misfortunes increase the fear reactions which tend to become panicky, but the establishment of successful adjustments at any stage tends to diminish the fear. If the misfortune be

great, or appears to be great in the mind of the one experiencing it, an emotional reaction may result to which we apply the term "morbid fear." It matters not at all whether either the danger or the disaster be real or imagined; so far as the fear reaction is concerned, the mechanism is the same. It is important to remember the fact that many morbid fears arise from misconceptions, and correcting the misconception may remove the fear.

A morbid fear might be defined as a fear which, considered in its entirety, is useless or unfavorable to the individual manifesting it. In applying this definition, it is necessary to evaluate the reaction in the economy of the individual. The warning of a rattlesnake may stimulate an alertness which serves to cope successfully with a real danger. If the same warning should cause an excessive fear reaction, or panic and futile, purposeless activities, the value of the reaction would be a negative quantity.

Every physician is dealing constantly with morbid fear reactions manifested by his patients. It is needless to attempt to classify or to enumerate them. They may occupy any position in the field of consciousness, from the fear which is fully recognized by the individual, to the fear reaction which is traceable to a disastrous experience long forgotten. The latter type is exemplified by the experience of a neurologist who suffered for many years an unaccountable fear of entering cellars, until an incident of his childhood was recalled to his memory. He had once been punished by imprisonment in a cellar closet, and although the fact of the punishment had been forgotten, the terror of the situation resulted in a morbid fear of cellars in general, and of dark ones in particular.

Fear reactions manifest themselves not only in varying degrees in different individuals, but also in varying degrees in the same individual at different times. A successful army is full of courageous soldiers, and a defeated one is full of neurotics. An individual enjoys motoring and the thrills of high speed and hair-breadth escapes until a disastrous crash is experienced. Subsequent motoring is likely to be punctuated by thrills not in the least enjoyable. The symptomatology of the victim of an accident is frequently complicated by exaggerated fear reactions based upon the same mechanism. A recent observation is illustrative: Three months previously the patient, a healthy young man of 22, entered a crushing-mill drum to make some repairs. While he was in it the power was turned on and he was tumbled about in the drum with loose pieces of metal for about one minute, the drum making twenty revolutions. He did not lose consciousness while in the drum, but was unconscious a short time after having been taken out. Although badly shaken up and covered with bruises, there were no broken bones or evidences of serious physical injuries. A severe neurosis, however, did develop, from which it will probably require several more months for him to recover. Besides the subjective symptoms and the many doubts and worries of the patient, there are apparent the pallor of the face and its drawn lines, sweaty hands, the excitable heart action, and the condition of undernourishment, which have developed during the course of the illness. It is probable

in this case that the fear reaction has been the most potent pathologic factor.

Favorable experiences, many times repeated at frequent intervals, tend to diminish excessive fear reactions. This rule is of fundamental importance in the treatment of the fear neuroses.

There is a close analogy between the mechanism of morbid fears and the state of allergy or tissue sensitization caused by an overdose of foreign proteid. Disaster or panic is followed by an increased sensitization to fear more or less of a specific type. This sensitization normally diminishes with frequent successful (non-harmful) experiences. Proteid poisoning is followed by tissue sensitization, also more or less specific, and which may be diminished by frequent, non-harmful doses of the proteid which caused the condition. Sensitization and desensitization are as real in the field of the emotions as they are in the tissues, and would seem to follow the same laws. It seems probable that a violent fear reaction must produce a definite physical change in the neurons and establish an easy channel for the flow of similar subsequent reactions which are quicker than thought in their occurrence.

The treatment of morbid fear reactions is too large a subject to cover in detail, but emphasis may be laid upon certain fundamental principles.

The first requirement in the treatment of morbid fear is a careful analysis, qualitative and quantitative, of the emotional elements of the individual problem. All sources of information should be followed to obtain complete history. The source of fears can generally be determined by careful effort, and they are mysterious only because they are unexplained.

The patient should be placed in an environment sufficiently protected to meet his particular needs, avoiding as far as possible conditions which react on him as harmful stimuli. In the beginning this protection should be as complete as possible, but it is not desirable that he should remain indefinitely so protected.

Education of the patient in the principles involved and in the true status of his own problem is often of great value, although it is not possible to put it to practice in all instances. Where fears are based upon misapprehension through ignorance, as they so frequently are, a true understanding is the best cure. A knowledge of the mechanism of fear reaction does not necessarily eliminate fear. This is one of the many instances in which intelligence does not control the emotions; but the emotions can be trained and habits established by intellectual controls, and in this connection emphasis may be placed upon moral courage and fighting spirit. Suggestion is useful in helping to establish the confidence of the patient, especially in calling his attention to encouraging and hopeful aspects of his situation. Exaggerated statements used in suggestion are bound to be harmful, and care should be taken to avoid purchasing hope for the present which is certain to be heavily discounted in the future.

It is easier to have courage when the physical vigor is high, hence attention to the general physical health of the patient is of utmost importance. The administration of sedative drugs to meet special

requirements serves a very useful purpose. Emergencies may be met and sleep regulated by comparatively harmless medication as well as by hydrotherapy, massage, and other common remedial measures.

It is desired to call attention particularly to the principles of sensitization and desensitization. Morbid fear is not cured, so long as special protection is necessary and a permanent protected environment is undesirable. Gradual desensitization may be accomplished by frequent experiences, in which the patient approaches a little at a time the object of his fear. It is the physician's function to set the scenery as well as possible that this may be accomplished.

When the patient has sufficient moral and physical stamina he will attain control of the situation, although the psychic trauma may leave a more or less painful scar.

1920 Wilshire Boulevard.

DISCUSSION

NATHANIEL H. BRUSH, M. D. (Santa Barbara)—Many years ago a well known neuro-psychiatrist said, "If you could eliminate alcohol, syphilis and fear from the human race, there would not be very much work for the psychiatrists to do." The passage of the Eighteenth Amendment has been a step towards the elimination of one of this triad, but the enforcement of the Eighteenth Amendment is still a long way from being perfect.

Syphilis can be controlled by education, treatment and prophylaxis. But until we can change entirely the minds and morals of men, syphilis will always be with us.

Fear comes to us through inheritance. Our instinct of fear can be traced back through the centuries and is our inheritance from ancestors who flourished in the neolithic ages. Fear can be considered one of the main driving forces that innervate our lives; that is fear of sudden death, escape from accident, etc., but the morbid fears that Doctor Ingham has spoken of can be considered as part of many of the well-known neuroses.

Cannon and other workers have given us an understanding of the physiology of fear, or rather what effect fear has upon the normal physiological processes. The previous speakers, during the afternoon, have dwelt upon this topic and its importance in the understanding of fear processes and conditions of fear.

Ingham has very cleverly likened the development of a morbid fear to the sensitization that the body undergoes upon contact with foreign protein substances, and the consequent reaction—allergy—to the formation of the fear.

The removal of the foreign protein or desensitization can be accomplished in the same way in the cases of morbid fears by opportunities in which the individual can meet and understand the nature of the causative factors of his fear.

In the treatment of patients in whom morbid fears are the predominating note it is quite necessary to have a complete and accurate knowledge of all the factors and circumstances that have played a part in the formation of the fear. All of these circumstances can then be linked up and the completed picture or chain of events can then be shown to the patient to help him to a better understanding of his condition and the causes of it.

As Ingham has said, "Favorable experiences, many times repeated at frequent intervals, tend to diminish excessive fear reactions." The importance of this cannot be too strongly emphasized. Again we can have recourse to the analogy of protein reactions.

THOMAS J. ORBISON, M. D. (2007 Wilshire Boulevard, Los Angeles)—I consider Doctor Ingham's paper a valuable contribution to the subject of the physiological effect of fear. Unfortunately, the "psychology of fear" has not yet been written. When it is, it will be one of the bases upon which the satisfactory administering of a large bulk of psycho-neurotics will be founded.

The one thing I wish to emphasize is that fear is one

of the three or four true emotions—if one hold with the dicta of Watson and other psychologists of his school. Also, it must be kept in mind that an emotion is the *consciousness* of a hereditary reflex (not necessarily the exhibition of it in terms of behavior). The afferent pathways are through the sense organs generally (during consciousness), although the origin may be a psycho-organic one. In either case the idea is the main element and the stimuli from it are supposed to be sent through the vegetative nervous system to the glands of internal secretion so that their response may prepare the individual to meet what may be necessary when he has become aware of whatever hereditary reflex that has taken place—be it fear, love, anger or whatever it may be.

Our treatment of the fear element is our psycho-neurotics, in order to be wise and according to scientific principles, must take these primary facts into serious consideration.

The results of our treatment, by whatever method carried out, will depend, to a large extent, upon how able we are to make use of them.

CHARLES G. STIVERS, M. D. (1115 Arapahoe Street, Los Angeles)—I would say a few words about fears and their removal from the minds of many of our speech-defect patients. Every person who tries to express himself, either in words or gestures or any other acts and makes a failure of it or even a poor showing, thereby starts in himself a fear that he may fail again if and when he tries again. All of the speech-defect persons have this fear to a striking degree. The stammerer fears that he will be ridiculous, and the aphasic that he will be thought feeble-minded or that he is talking "baby-talk." The removal of these fears must be undertaken by patient analysis of the cause of the fear, and showing the patient that there is no basis for the fear. It is a well-known fact that so-called morbid fears have no rational basis for their existence or, at most, very little basis. I "drag the fears out into the open" and turn the light of reason and common sense on them and they will disappear. The subsequent treatment consists in substituting a good habit of expression for the former bad one by drills, talks, repetition, etc., going from easy things to more difficult ones.

DOCTOR INGHAM (closing)—*Psychology*, except for the homemade or instinctive variety, has not yet come to be established on a sound, scientific and practical basis, as applied to the practice of medicine. Everyone takes a try at it, and in the public mind a fanciful theory is particularly attractive.

The advance of modern medicine has been almost exclusively along the line of physical science. It would seem that a study of psychology, and particularly of the emotions from the biologic and scientific standpoint, offers the best prospect of real progress in this field. Fears, exaltations, instincts, habits, ideals, endocrines, and physiologic reactions are only items in the field. We need not only some simple practical working formulae for the physician to use, but a conception of the factors present, each in relation to the other.

October 27, 1925.

Dear Editor—I presume it is too late to have inserted in the next issue of CALIFORNIA AND WESTERN MEDICINE a notice that Dr. Putti, the Lane lecturer, has consented to give a clinic on Thursday, November 12, 1925, at 11:30 a. m., at Lane Hall, during the course of Lane Medical Lectures. Very truly yours,

W. OPIULS, *Dean*.

[We were very glad to have this space open in which to insert the above interesting notice.—EDITOR.]

"California's experience has been that, once in possession of a drugless license, a surprising number pose as doctors of medicine, surreptitiously violating that provision of our medical act which prohibits a drugless practitioner the use of drugs. Laws governing evidence are so adroitly drawn that it is difficult to obtain 'admissible' evidence which will 'pass muster' in a court of law, hence prosecutions have been few."—*Charles B. Pinkham in Federation Bulletin, Aug., 1925.*

MUCOCELE OF THE FRONTAL SINUS CAUSED BY AN OSTEOMA

REPORT OF A CASE

By J. A. BACHER, M. D.

Report of a case.

Discussed by Harold A. Fletcher, San Francisco; Francis L. Rogers, Long Beach.

OSTEOMA of the frontal sinus is not rare; nor is mucocele of the frontal sinus. But osteoma as a cause of mucocele is. Howarth, in recording a case, has not been able to collect as many as twenty cases. I operated on such a case in 1921, and wish to record it on account of its rarity. My own case is as follows:

Male, 25. Salesman. Headache, six years.

P. H.—Impairment nasal breathing, years, relieved by swimming in salt water. Not frequent acute rhinitis. No excess post-nasal discharge. Not frequent sore throats. Never any discharge from or pain in ears. Six years ago, struck on left orbital region by baseball.

P. I.—*Left* frontal headache for about an hour daily for past six years, usually at midday, increasing in frequency and intensity. No relation to work or use of eyes. Often coincident with nasal obstruction, flushed face. Left eye becomes red during attacks.

P. E.—There were no external deformities or swellings to indicate the presence of a tumor. Nose: External deformity, nasal bones to right, tip to left. Septum markedly deflected to right, turbinates engorged, no pus seen, poor space. Septum irregular on left, no pus seen, good space. Throat: Tonsils moderate size, wide crypts, purulent debris in crypts. Nasopharynx: Clear. Ears: Both membranae tympani retracted, slightly fibrous. Washed both antra with trocar through inferior meatal wall, and fluid returned clear. X-ray of sinuses: "In the *right* frontal sinus, an opacity definitely interpreted as due to an osteoma."

Operation—Brow not shaved. Killian incision. Right frontal sinus entered externally, keeping away from site of osteoma. Upon penetration of outer table, greenish-blue thick membrane as of mucocele presented, filling sinus. Membrane incised and thick, yellow fluid evacuated. Culture made which showed "a scanty growth of streptococcus." Heavy lining of sinus removed, and tumor revealed, seeming to present on outer table at superior junction of inner and outer table. Bone of outer table removed up to attachment. Probe reveals that it is a sessile tumor with attachment superiorly, anteriorly, posteriorly, and internally, as if crowded up into the supero-internal angle of sinus. Very eburnated and regular in shape. Unable to pry it off. With chisel removed it from its attachment, which was most firm posteriorly. Removal revealed a depression of inner table caused by tumor, partly in right sinus and partly in left, as there was no septum between the sinuses. No dehiscence in this depression, but bone felt very thin. Probe passed freely through ostium frontale, into nose. *Frontal ostium and ethmoid cells not curetted.* Wound closed tightly with six silkworm sutures. No drain. Benzoin dressing. Convalescence: On account of swelling at outer angle of incision, it was opened and small drain used for four days. Closed. Absolutely free from headaches for over three years now since operation.

Microscopical Examination by Dr. F. E. Blaisdell—"Osseous tissue, in which the trabeculae are very irregular, most widely separated in the central area, becoming thicker and more compact peripherally beneath the periosteum, here the marrow spaces are reduced more or less to a minimum size. There is no distinct cortical layer, other than that formed by the compact and very irregular trabeculae, which even here exhibit variation in thickness, for in places the wider marrow spaces attain the surface beneath the periosteum. No true cortex (compacta) is recognizable. The surface is invested by a thin fibrous periosteum. The marrow spaces are filled by a fibrous marrow. At one point of the surface the osseous

tissue projects, and here shows a distinct lamellated structure. This is evidently the remains of the pedicle by which the growth was attached to the wall of the sinus.

Microscopical Details—The trabeculae stain irregularly, part of them take the eosin and are apparently osteoid in character; elsewhere the hematoxylin staining predominates and varies in intensity, delimiting irregular and more strongly calcified areas. Lacunae are everywhere present and empty, except in and about the pedicle, where each contains a bone cell and lamellization is distinct and quite normal. Careful examination under high, dry magnification shows the presence of an imperfect canalicular system. Trabecular lamellae are entirely indistinct, imperfectly and vaguely indicated, or distinct; the latter observed chiefly in the osteoid or eosin-staining trabeculae. In the superficial and condensed area an occasional Haversian canal seems to be present, surrounded by the concentrically arranged lamellae with intervening lacunae. Bone cells are only observed in the lacunae of the pedicle. There is distinct evidence of destructive and constructive changes having taken place during the growth of the tumor, for in places the deeply stained calcified trabeculae end abruptly against very irregular edges of the osteoid areas. The irregular edges of the osteoid tissue indicate the past activity of osteoclasts.

In the series of sections studied the marrow is fibrous throughout. Differential staining shows the presence of collagenous fibrils and bundles. Marrow cells are entirely absent, unless a few scattered and poorly stained cells

Figure I. Two days after operation

Figure II. Six months after operation

Figure III. Osteoma, natural size

Figure IV. Photomicrograph. Zeiss: Oc. 4; obj. 1 inch (B. & L.)

be such. Osteoblasts and osteoclasts are absent. Blood-vessels have not been recognized. Diagnosis: Osteoma (osteoma spongiosum)."

DISCUSSION

HAROLD A. FLETCHER, M. D. (Butler Building, San Francisco)—Either mucocoele or osteoma of the sinuses is always interesting. Those of the frontal and ethmoid sinuses, because of their complicating features, are most interesting, while mucocoele of the frontal sinus, with osteoma as the etiologic factor in its production, is most interesting and most rare. It is even more rare than the author has quoted, as my interpretation of Howarth's series is, that, of his twenty cases of mucocoele, only one had osteoma as the etiologic cause.

Osteoma of the anterior ethmoids or of the region of the floor or duct of the frontal sinus would, in its very nature, by its slow but steady increase in size and pressure, most surely cause absorption of the frail bony partitions here, and soon occlude the frontal duct and cause a mucocoele.

Clinically the differential diagnosis between osteoma and mucocoele is difficult, except by the careful study with the x-ray. The x-ray, of course, clinches the diagnosis. Where both are present, as in this case, the diagnosis would be osteoma, from the x-ray findings. Mucocoele apparently was not diagnosed until operation.

It is a pleasure to have a careful and complete pathological report with such a case as this. Too often the diagnosis of osteoma or some such tumor is made at operation from the gross specimen, and no study made of the pathology. A review of the literature would reveal many such cases, and only a very occasional study of the microscopical picture, with a view ever present of determining the cause of this new growth, as well as other types. Eckert mentions this in his study of osteoma of the nasal fossa. His pathological reports agree with the pathological report of Dr. Bacher's case.

FRANCIS L. ROGERS, M. D. (Markwell Building, Long Beach, Calif.)—Such contributions as this from Doctor Bacher are, I believe, valuable because both osteoma and mucocoele of the sinuses are undoubtedly less rare than our past and present literature would lead us to believe.

Whether the tumor is a mucous polypus, a retention cyst, or bony growth in the frontal sinuses, there is the symptom of more or less constant pain, headache. The numerous cases of frontal headache met with which do not yield to refractive corrections or general treatment and give no adequate nasal symptoms should suggest to us all to routinely secure x-ray and other modern diagnostic measures in our search for intrasinus tumors. In mucocoele of the polypoid type it is my impression the fluid contents are usually sterile, unless the tumor sac has been ruptured, while the retention cyst type are apt to contain infective organisms of the staphylococcal or streptococcal types with some previous drainage to the nose or elsewhere. Early recognition of these conditions is quite important because of the fact that pressure from the mucocoele may cause extensive absorption of its adjacent normal bony structures.

A case in point was recently seen by me here in a woman, age 56, whose primary complaint was a badly swollen left eye. There was no history of injury, but extensive ecchymosis of eyelids and marked exophthalmos, and a very profuse muco-purulent discharge. The discharge was found to contain both strep and staphylococci, but no gonococci, as was first suspected. A deep central corneal ulcer was present, and perforation to the anterior chamber and infection had already taken place, rendering the eye hopelessly lost. A distinct fluctuating tumor in the ethmoid region of the orbit was readily made out, which, on pressure, provoked added discharge of a heavy, pale yellow muco-purulent character from under the upper eyelid. The throat and nasal passages appeared free from disease or bony deformity, and there was no history obtainable of rhinitis or other disease from patient or relatives. She was removed to the hospital, where x-ray plates were taken, indicating a complete filling of the left frontal sinus with a fluid deposit. The eye was enucleated and a digital examination of the orbit revealed the fact that almost the entire fronto-orbital wall had been dissected out, not by necrosis, but

evidently by the absorption, due to intra-frontal pressure from a soft fluctuating tumor. A later operation confirmed the fact that the frontal sinus was filled with a large mucocoele. The mental state of this patient was that of a moderately advanced case of senile dementia, which was suspected might be due to pressure from extension of the mucocoele into the cranial cavity. But this was not confirmed at the frontal sinus operation, and the report from the laboratory of a 4 plus Wassermann indicated that the mucocoele had probably little or nothing to do with the mental condition. This patient made a slow but uneventful recovery, and is able to wear an artificial eye. Under suitable medication her mental condition has also improved somewhat.

DOCTOR BACHER (closing)—As to the frequency of such cases, Howarth's words are: "Osteoma, however, as a cause of mucocoele is rather rare. Cases have been described by Luc, Laurens, Axenfeld, and others, but I have not been able to collect as many as twenty."

BLOOD TRANSFUSION

By GEORGE H. JUILLY, M. D., *San Francisco*
(*From the French Hospital*)

Long before Harvey's discovery of the circulation of blood, physicians had tried to rejuvenate old men by introducing into their veins the blood of young and vigorous individuals.

Blood transfusion is especially effective in patients who have become acutely anemic, as the result of a large and sudden loss of blood—hemorrhage from childbirth, gastric ulcer, intestinal, kidney and bladder hemorrhage, epistaxis, internal hemorrhage.

The only blood which needs to be considered is human blood, properly typed and carefully examined.

There is no question that the whole blood transfusion is superior to the citrated blood method.

DISCUSSION by R. F. Grant, Alson R. Kilgore, A. N. Fregeau, W. J. Hawkins, E. S. Kilgore, J. K. Plincz, H. Marcus, *San Francisco*.

BLOOD, as a therapeutic agent, has been used from the remotest antiquity. Men have not been slow to discover that when a wounded man lost too much blood he would die. Consequently, they reasoned out that blood was not only necessary to life, but that life itself—or the soul—was more or less concentrated in that blood. This fact explains why in all mythologies—those of the North especially—the drinking of blood was considered beneficial, just as eating the heart of ferocious animals and of man at times was thought to impart the strength and the courage of the animal from which it had been removed. This is still a common belief among the savages of Central Africa and the Bushmen of Central Australia.

But as the embalming of the dead in Egypt and the killing of various animals on the altars of Gaul, Greece and Rome had given men a certain understanding of anatomy and physiology, they began to search for a means of transfusing pure blood into the veins of the patient, rather than making him drink it, which showed no apparent benefit.

Of course, they found no way of accomplishing this, until Harvey discovered the circulation of the blood in the middle of the seventeenth century.

Yet, the actual drinking of blood for the cure of disease has not died down; and I remember very well when anemic patients and the consumptive were directed to the slaughterhouse for the purpose of drinking fresh, warm blood.

But formerly blood was thought of not only as

a marvelous therapeutic agent in the cure of disease; it was also thought to have great power to rejuvenate the old. This is another example of a human desire, hoary with age, which has at different times given us the good fairies changing old men into young princes; which has given us Faust selling his soul to the devil; Ponce de Leon looking for the Fountain of Youth, and has lately enticed some of our old, astute and successful business men to submit to an intimate contact with the all-magical monkey gland.

Long before Harvey's discovery of the circulation of blood, physicians had tried to rejuvenate old men by introducing into their veins the blood of young and vigorous individuals. The Latin poet, Ovid, in his *Metamorphoses*, has Medee address herself to the sons of King Pelops, whom she wanted to rejuvenate. "Draw your swords, let that old man's blood run out: I will replace it in his veins by a young blood."

Later on, toward the end of the fifteenth century (in 1492) Sismondi says that the Pope Innocent VIII, being very ill, an attempt was made by his Jewish physician to inject into his veins the blood of three young men. All the young men and the Pope himself died.

Libavius, in 1615, says: "Let there be present a robust, healthy youth, full of lively blood. Let there come one exhausted in strength, weak, enervated, scarcely breathing. Let the master of the art have silver tubes that can be adapted one to the other; let him open an artery of the healthy one, insert the tube and secure it. Next let him incise the artery of the patient and put into it the feminine tube. Now let him adapt these two tubes to each other and the arterial blood of the healthy one, warm and full of spirit, will leap into the sick one, and immediately will bring to him the fountains of life and will drive away all languor."

After Harvey's discovery, blood transfusion became a regular procedure. In 1666, Lower gave the process in detail. In 1667, J. B. Dennis of Montpellier, physician to King Louis XIV of France, is said to have successfully transfused into a patient nine ounces (250 cc.) of arterial blood taken from a lamb. This apparent success had an unfortunate sequel. Many doctors tried this operation for the cure of the most varied diseases, with dire results, as was to be expected (only 87 out of 785 being successful). The authorities became alarmed, and in 1668 the Chatelet rendered a decree forbidding anyone to try blood transfusions, without securing the approval of the Faculty of Medicine.

This operation, therefore, fell into disuse and was not revived until the nineteenth century. Blundell, in England, spoke highly of it. Blasius (1863) reported 116 cases in the previous forty years, with fifty-six successful results (in two cases serum from animals was used). Enthusiasm was again aroused, but died down after Landois showed that heterogenous blood could not be used because of red cell destruction, and Blasius' defibrinated blood was found dangerous because its fibrin ferment caused coagulation.¹

¹ After G. Witrowski. *Le corps humain*, third edition, 1884.

In 1875, normal salt solution was discovered, and blood transfusion fell into disuse again; although it was revived five years later by W. S. Halsted, who used it on several patients suffering from carbon monoxide poisoning.

In 1880, Voisin used sheep's blood, defibrinated by whipping, to transfuse insane people who refused all nourishment.

Other fluids than blood have been used, milk being one of them, but normal salt solution has been the most extensively used of all for that purpose. But while this process furnishes the necessary bulk to the arterial and venous systems, yet it dilutes the blood corpuscles to such an extent that the urgently necessary function of carrying oxygen and carbon dioxide is much perturbed.

It was readily seen that, while salt solution was a good and rapid stimulant, its action was ephemeral and that it could not compare with blood transfusion for permanent and curative effects.

Through the work of Crile and Carrel in this country, blood transfusion has been revived and made safe. However, their methods of directly connecting the circulatory system of the donor with that of the patient have fallen into disuse, mainly from the fact that the exact amount of blood passing from the donor to the patient could not be ascertained, even within wide limits.

For that purpose Crile used to join the radial artery of the donor to the median-basilic vein of the patient by means of a little tube of german silver. Carrel used to anastomose both vessels directly by suture with fine vaselined silk. Brewer used pieces of well-paraffined glass tubing for the same purpose. Levin, in 1909, described a very ingenious forceps with two small conical extremities (one holding the vein, the other the artery) so that when the forceps was closed both vessels were in intimate contact, much the same as two pieces of intestines are held together in a Murphy button.

Today these methods have become obsolete. We want to know the exact amount of blood we give the patient. To accomplish this result, it is necessary to receive the donor's blood in a graduated vessel and transfer it into the patient's circulatory system.

Blood transfusion is especially effective in patients who have become acutely anemic as the result of a large and sudden loss of blood (hemorrhage from childbirth, gastric ulcer, intestinal, kidney and bladder hemorrhage, epistaxis, internal hemorrhage).

It is not quite as effective, although having considerable value in repeated small hemorrhages from whatever source.

It is much less effective in primary anemia (pernicious) or in secondary anemias, due to disease (tuberculosis, cancer, sepsis, etc.).

In order for the patient to get the full value of the transfusion, it is necessary that the source of bleeding be arrested, otherwise the transfusion seems to increase the hemorrhage, and in a short while the patient is no better off than he was before.

The only blood which needs to be considered is human blood, properly typed and carefully examined.

SELECTION OF THE DONOR

The donor should be a strong healthy adult. His blood should have been carefully tested for syphilis, while he or she should be free from all tuberculous or malarial taint.

Yet, a very small quantity of blood from such a healthy individual may kill the patient. This is due to certain qualities of his blood corpuscles, which may be agglutinated by the patient's serum, or else his serum may agglutinate the patient's corpuscles. This, of course, results in speedy death. Hence, the absolute necessity of typing the blood of all donors and recipients before making any transfusion.

The blood of individuals has been divided into four groups ²—groups 1, 2, 3, 4.

The following table shows this grouping, as devised by Moss:

Sera of recipient			
Group 1 10% (— means agglutination.)	Group 2 — 40%	Group 3 — 7%	Group 4 — 43%
Corpuscles of donors			
Group 1 — + + +	Group 2 — — + +	Group 3 — + — +	Group 4 — — — —
(— means no agglutination.)			

Group 1 is the universal recipient. Any donor is good.

Group 2, recipient, can be transfused only by blood of Groups 2 and 4.

Group 3, recipient, can be transfused only by blood of Groups 3 and 4.

Group 4, recipient, can be transfused only by blood from Group 4.

It is to be noted that *Donor Group 4 is the universal donor*, as his corpuscles are not agglutinated by any serum.

It is not my intention to describe here the technique of such grouping; this may be found in any modern book on laboratory technique.

It is to be noted, however, that such grouping and blood testing takes time, whereas a blood transfusion generally partakes of an emergency character.

It is, therefore, customary in large hospitals to have a list of a certain number of professional donors who have been properly typed and who can be reached and made ready with a minimum of delay.

If no such donor is at hand and you are in a great hurry, almost anyone can serve as a donor (barring the syphilitic, the tuberculous, and the malarial). Agglutinating accidents are, fortunately, rare, being less than 2 per cent. If you have a little time it is always wise to follow the Jeambrau and Giraud's technique.

First. Take 2 cc. of blood *from the patient* and collect it in a sterile dry test tube. Let it stand four or five minutes. The serum floats over the clot.

Second. With a *well-citrated* Luer syringe aspirate about 1 cc. of said serum, and deposit a few drops of it on two dry glass slides.

Third. Get a few drops of blood *from the*

donor's ear and, bringing the slides next to his ear, quickly mix one drop of blood each in the drops of serum laid on the glass slides.

4. If the drop takes a uniform reddish color and dries with the center a little darker than the periphery, there is *no agglutination* and the *donor can serve*.

Fifth. If the drop of serum remains clear while little colored masses float in it, *there is agglutination*, and the *donor* is unfit.

This agglutination, or the lack of it, can be still better determined by looking at the drop on the slide through the low power of a microscope.

TECHNIQUE OF BLOOD TRANSFUSION

Numerous methods have been devised to obviate the clotting of the blood while it is transferred from one individual to another. I will describe only two methods, which are very simple and give equally good results.

There is no question that the whole blood transfusion is superior to the citrated blood method, but it is also a little more difficult, and beginners will do well to practice the latter method a few times before attempting the former.

CITRATED BLOOD METHOD

This method is based upon the fact that sodium citrate, added to the blood in suitable proportions, will prevent the latter from clotting for a very long time.

One should have ready the following paraphernalia:

First. A six-ounce bottle full of sterile 2 per cent solution of sodium citrate.

Second. Two tourniquets and clamps (or Kellys).

Third. Two sterile graduates of 500 cc. with some glass rods.

Fourth. One sterile glass funnel, with two feet of rubber tubing and a stop-clamp on it.

Fifth. A good size trocar; one transfusion needle (which will fit on the rubber tubing).

Sixth. Two sets (one for each patient) containing a scalpel, two thumb forceps, some fine Kellys, scissors, some fine curved needles with Dermal and needle holder, some pieces of fine catgut, etc. All properly sterilized and dry.

A few Luer syringes; some sterile salt solution and sterile towels should be near at hand.

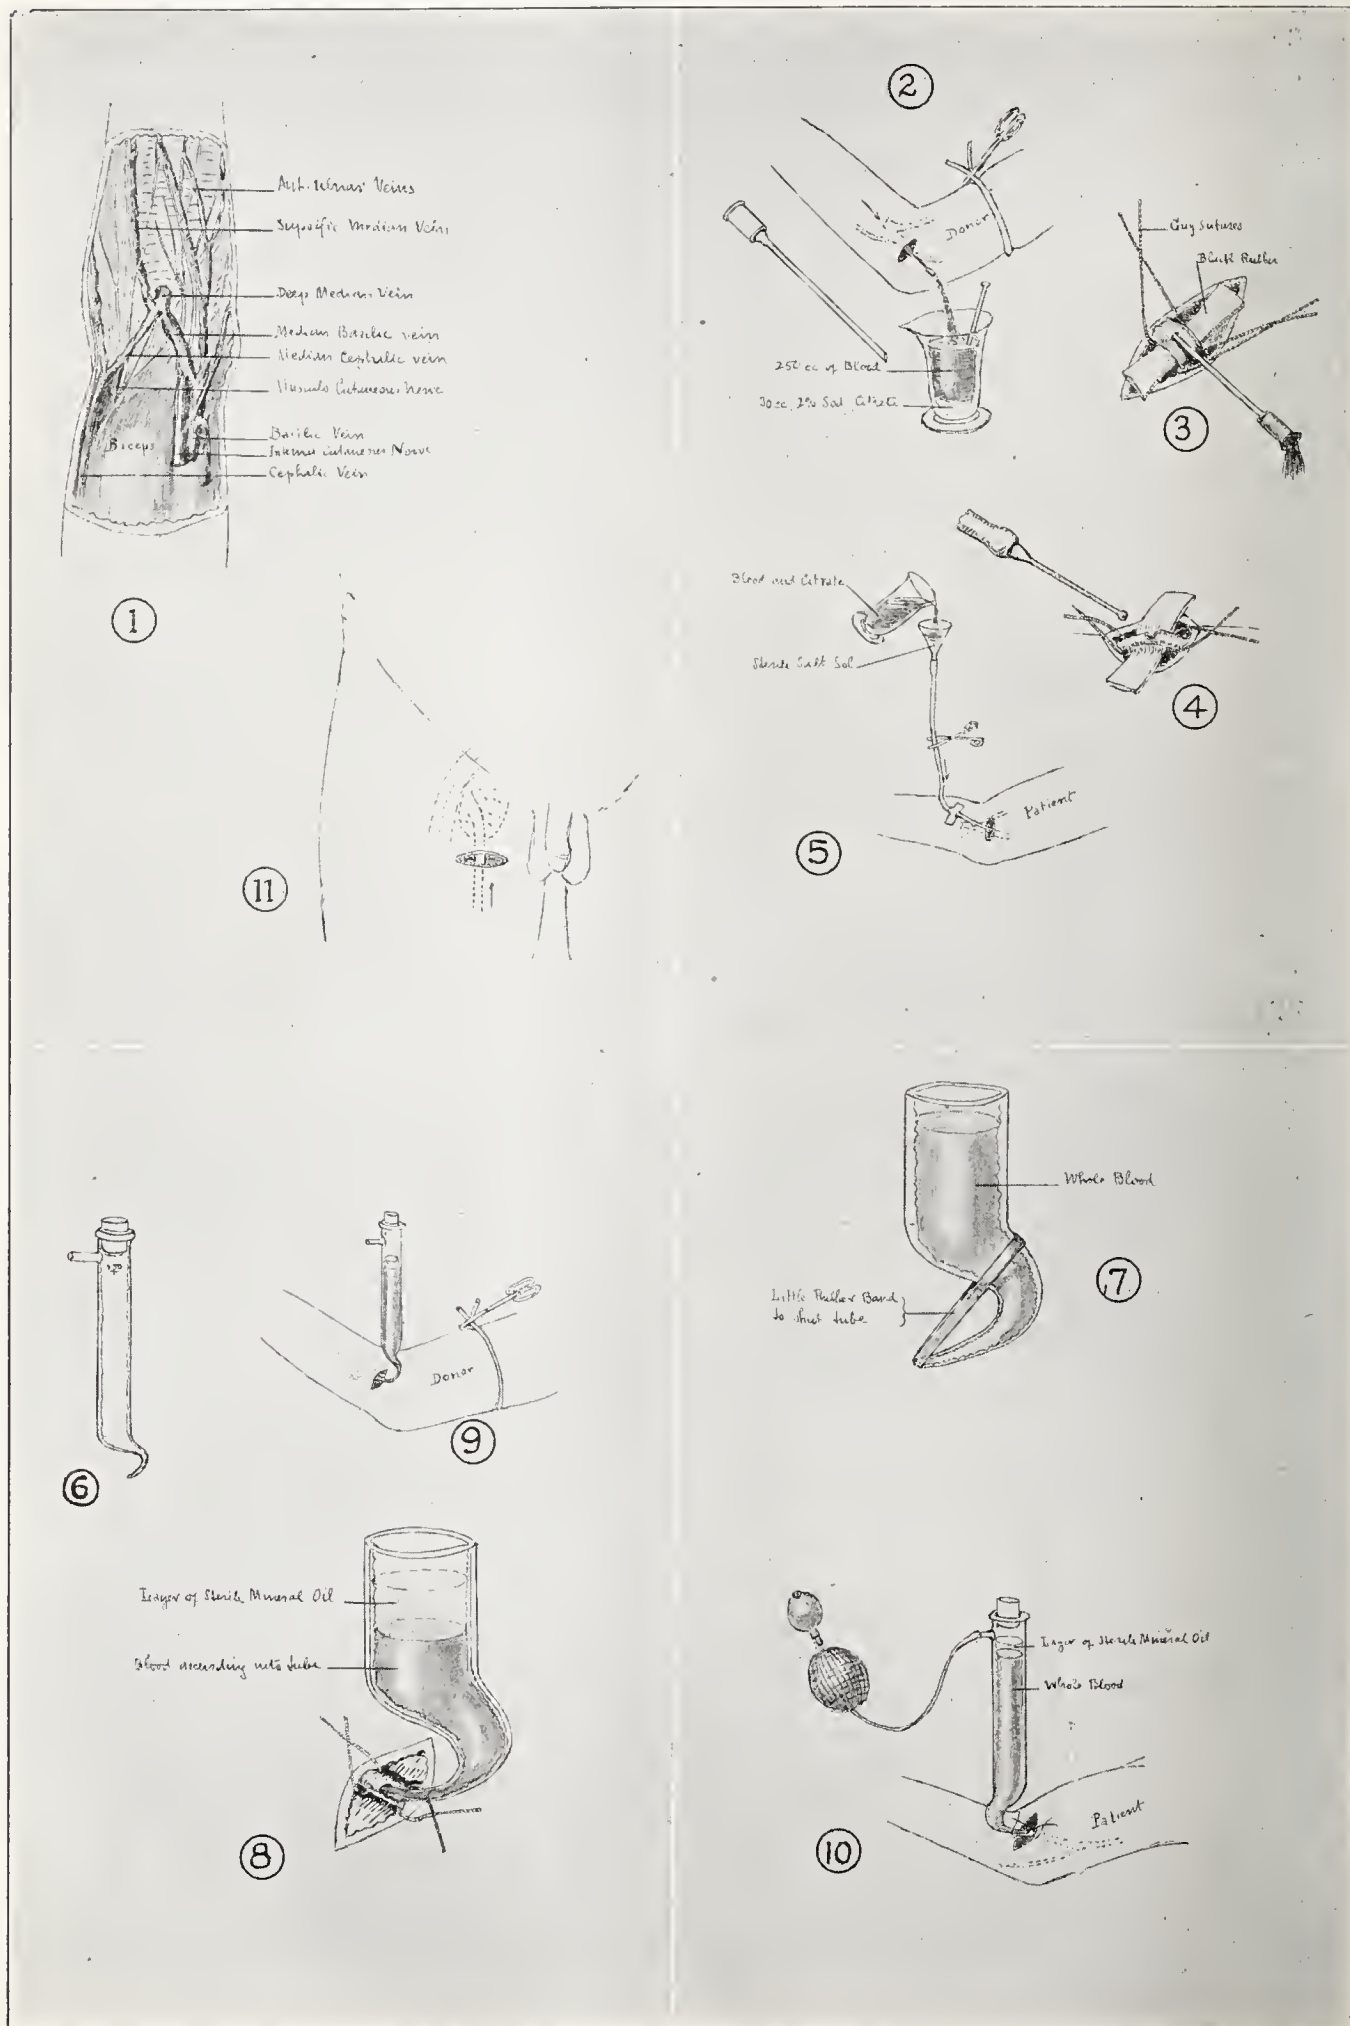

Have patient and donor brought into the operating room, laid upon two tables, properly draped; the arms of both patients opposite each other, each arm resting on a small table at a short distance from each other. The arms showing the largest veins should have been selected (Figure 1).

The surgeon and a good assistant (two good assistants are still better) with one or two nurses should pass through the process of sterilization, as for a major surgical operation.

When everything is ready a 3 per cent tincture of iodine solution is painted on the arms of both donor and patient, the hands and shoulder being covered with sterile towels.

You place the tourniquet on the donor's arm. Do not tighten it enough to stop the arterial circulation. Freeze the fold of the elbow with ethyl

² Victor D. Lespinasse. Blood transfusion. Surgical Clinics of Chicago, February 1919, page 37.

chloride spray (or inject 0.5 per cent solution of novocaine) and make a transverse one centimeter incision over the median cephalic vein (Figure 2). Remove from the vein all adventitious tissue. Place a little flat piece of black rubber tubing under the vein; the contrast between the black and pink vein makes the latter stand out better (Figure 3).

Do not start to draw the blood yet—until you have made sure of finding a proper vein in the patient, and that such vein is patent.

Then repeat the same process on the patient's arm, to save time. When the patient's vein has been exposed, pass two catgut strands around the vein, but do not tie them. To make sure that the patient's vein is patent, you may now inject a few centimeters of salt solution with a Luer syringe and a small hypo needle. If the solution runs freely, everything is ready for the transfusion.

Have a graduate ready; put 30 cc. citrate solution (enough for 250 cc. of blood) in it with a glass rod. Bring the graduate near the donor's arm, steady the vein and plunge the trocar into it, the point toward the donor's hand. The blood flows into the graduate. Have the donor close and relax his fist all the time. The muscular contractions help the blood to flow. Have the assistants refrain from talking. This may cause the donor to faint. The assistant or a nurse stirs the blood and solution together with the glass rod until you have collected 250 cc. of blood.

This blood being properly citrated will not coagulate. If you wish to transfuse 250 cc. of blood only, your assistant will tie this donor's vein with a catgut ligature above and below the opening, and suture the skin wound. If you want to transfuse more blood, he will use the second graduate and repeat the same process while you transfuse the blood into the patient.

To transfuse the patient, fit up the funnel to the rubber tubing, at the other end of which is fitted the canula. Fill up said funnel with warm salt solution, which you allow to run through the canula in order to force out all air bubbles from the tubing. When you have done this, put the stopper on the tubing.

Steadying the patient's vein with the two strands of catgut, make a nick into the vein with a pair of fine scissors; insert the canula into the vein, the tip toward the patient's shoulder (Figure 5). Tie the vein over the tip of the canula with the upper catgut; while the lower catgut closes the lumen of the vein below. Remove the stopper and allow the salt solution to run into the patient's vein. Now pour your citrated blood into the funnel—either 250 or 500 cc, as desired. The operation should take about twenty minutes. When completed, another ligature is passed on the vein above the canula, tied, and the vein cut below, thus releasing the canula. The little skin wound is closed with two dermal sutures.

The effect of a transfusion in a patient who has suffered from a large hemorrhage is immediate and astonishing. The lips become red, the face is flushed, the patient experiences a feeling of glow all over and an indescribable sensation of well-being.

However, some patients show some reaction dur-

ing the first twelve hours—transient dyspnoea, headache, cyanosis, and nervousness. While some of these symptoms may be due to a proteid intoxication, they are often due to a defect in technique—poor asepsis, entrance of air into the veins, and, especially, too large a quantity of citrate being used.

In reference to the last mentioned mistake, it is easy to figure out how too much citrate may be injected. It happens occasionally that you cannot get 250 cc. of blood from the donor. He may faint during the process; this stops all bleeding. Suppose that you get only 100 cc. of blood. You do not want to lose it, and you transfuse it into the patient's vein. But at the same time you inject 30 cc. of citrate contained in the graduate, or nearly three times as much as would be necessary to prevent coagulation of 100 cc. of blood. This extra citrate is going to affect the patient's blood and disturb its proper function—hence some of the untoward symptoms recorded—until nature gets rid of the drug through the kidneys. The latter are more or less irritated, as evidenced by reddish urine, with albuminuria, rare hyaline casts, edema of face and hands, and headache. This, fortunately, passes off in a day or so.

If one should be unfortunate enough to use a donor's blood, causing agglutination (through a mistake in the laboratory test) your patient is doomed. He is immediately taken with intense dyspnoea, deep cyanosis with arrest of respiration, then of the heart beat, speedily followed by death.

You may try artificial respiration with the pulmotor, external heat, injection of adrenalin (1 cc. at a dose), dilation of the anal sphincter, etc.

To prevent such a tragedy, however rare, it is best, in starting the transfusion, to stop it after a few cc. of blood have been allowed to enter the patient's circulation, and wait a few minutes.

If any of these symptoms manifest themselves, stop immediately and apply some of the remedies described above. If nothing happens, proceed with the transfusion.

WHOLE BLOOD TRANSFUSION

In this case no citrate is used. Other means are taken to prevent the donor's blood from coming in contact with the air. Speed in all the steps of the operation is also a great factor in its success, consequently this method should not be attempted until the surgeon and his assistants have mastered all the little details of a citrate transfusion.

The paraphernalia needed are much the same as those required in a citrate transfusion, except that the graduates are replaced by special glass cylinders. These have been carefully coated beforehand by allowing paraffine to melt in the cylinder heated in a dry oven, thereby covering the walls with a fine film. This operation should be done carefully, so that no bare glass wall will be present. Care should also be taken to see that the beak of the cylinder is not obstructed by the paraffine. Two of these 250 cc. cylinders are made ready for an ordinary transfusion (Figure 6).

Also have ready a thermo-cautery bulb with its rubber tubing and some sterile Russian oil—the

same kind that is used for the relief of chronic constipation.

It is my custom to put about 10 cc. of this Russian oil in each glass cylinder before starting the transfusion. Its use will be explained a little later on.

When everything is ready, the vein of the donor and the vein of the patient are exposed. Two strands of the fine catgut are passed around each vein, and a piece of black rubber placed under it for better contrast.

The distal catgut ligature on the vein of the patient is now tied, the vein half severed above said ligature (Figure 4), and the edge of the cut vein grasped by two fine Allison forceps. To prevent bleeding from the vein the assistant pulls upon the upper catgut strand against the edge of the skin. Now return to the donor. The same procedure is followed with his vein, which is half-severed. The upper part of the vein is held by two fine Allison forceps. Now, with your left index finger upon the beak of the cylinder (to prevent the escape of the mineral oil) or a rubber band (Figure 7) bring it close to the vein, remove your finger, and quickly plunge the conical tip of the cylinder into the vein. The blood will immediately begin to flow into the cylinder, the mineral oil floating on top of it, thus preventing any contact with the air contained in the cylinder. The donor activates this bleeding by rhythmically closing and opening his fist (Figures 8 and 9).

When the cylinder is filled remove it and quickly place your index finger upon the tip, to prevent any loss of blood. Your assistants shut off the flow from the vein by pulling upon the guy ligature, or else fill up the second cylinder while you are injecting the first one.

Bringing your cylinder full of blood to the patient, you remove your finger from the beak while you quickly introduce it into the patient's vein. The blood may flow of its own accord. If it does not, adapt the cautery bulb to the glass extension and have a nurse blow once or twice. This starts the blood going nicely. Do not allow it to transfuse too fast (Figure 10).

Repeat with the second tube if you wish to transfuse 500 cc. When all is finished, tie the proximal ligatures around the vein of patient and donor and close skin wounds with a couple of dermal sutures.

This I have found to be the best procedure. The fewer needles, tubing, syringes, etc., that you use the less chances you have of clotting the blood, which is the condition *sine qua non* of a successful issue.

NOTES ON TRANSFUSION

While the bend of the elbow is generally chosen to isolate a vein for a transfusion, there are cases when some other part of the body must be chosen for the same purpose.

Some individuals, even adults, seem to have very small veins. This is often the case in women, especially those who show a tendency to obesity. Looking for a vein in these donors is often quite an undertaking, and, when found, the vein is so small that it cannot be used.

Again, in some patients who have been rendered

very anemic by hemorrhage—just the type who need a transfusion—the peripheral veins seem to be flattened, and although their size has not had time to diminish, to find these veins is not always easy.

Again, in infants and children the arm veins are so small that they cannot be used in a transfusion.

In babies the anterior fontanelle can be used very nicely. The blood is generally taken from the mother (20 cc.) by means of a warm Luer syringe, well lubricated with sterile mineral oil or with citrate solution.

In older children the fontanelle is closed and the arm veins are too small. Recourse must be had to the external jugular vein, or to the internal saphenous vein (Figure 11).

The internal saphenous vein lends itself very nicely to a transfusion in adults when the arm veins cannot be used.

Ligating, cutting and otherwise destroying the median cephalic or median basilic veins is generally of little import to transient donors. But the same cannot be said of professional donors.

Some of these seem to make a living by selling their blood. One of them is recorded who was used nearly 150 times in the space of two years among the Chicago hospitals. In these people, preserving their arm veins is absolutely essential.

Instead of cutting the vein clear through, as is done with a transient donor, puncturing it with the trocar to collect the blood is all that is necessary in the citrate method.

In the whole blood method the vein is simply cut half-through with a delicate pair of scissors (Figure 4) to allow the introduction of the beak of the glass transfusion tube.

Tying the vein above and below the perforation with a fine catgut ligature stops all bleeding. When the catgut is absorbed, nature reopens the lumen of the vein in a short time.

In selecting your vein from a donor, be very careful not to plunge your trocar near a vein anastomosis, or else you will be troubled by constant oozing during the operation.

Sometimes blood may be secured from the patient himself. I mean that in certain cases of internal hemorrhage the blood found in the abdomen may be collected, received in graduates, properly citrated, and reinjected into the patient's circulation.

133 Geary Street.

DISCUSSION

DR. R. F. GRANT—I once watched a blood transfusion in which the patient died in two minutes after 100 cc. of blood had been transfused. I believe that not only should the donor of a proper group be selected, but that proper matching should be done just before the transfusion.

ALSON KILGORE—While the Mors grouping of human blood is fairly accurate, some groups seem to have subdivisions which, if not detected in time, will cause dangerous symptoms of agglutination.

A. N. FREGEAU—Could not some other form of anaphylaxis cause the dangerous symptoms complained of besides agglutination? Could not the anaphylaxis of certain proteids contained in the donor's serum account for some severe reaction observed at times, even with proper group and matching?

W. J. HAWKINS—The fact emphasized by Dr. Juilly of stopping the source of the hemorrhage before expecting

good to follow a blood transfusion is well illustrated in the case of fibroids of the uterus. If the hysterectomy immediately follows the transfusion, good will have been accomplished. But if the transfusion is not followed by curative measures, bleeding from the fibroids will be increased, and in a day or two the patient will be no better off than before.

E. S. KILGORE—This is what I have observed in certain cases of hemorrhage from a perforated ulcer of the stomach. The transfusion seems not only to start the hemorrhage anew, but, to my mind, the patient will die as a result of this procedure.

I would like to ask Dr. Juilly if in all cases of internal hemorrhage the extravasated blood could not be used for transfusion into the veins of the patient?

J. K. PLINCZ—Has Dr. Juilly ever used the De Lee transfusion apparatus? It seems so simple, that it should be a real improvement over the described methods.

H. MARCUS—What precaution should be taken in transfusing an infant through the fontanelle?

G. H. JUILLY (to close)—Agglutination during a transfusion is such a tragedy. We are so helpless when it occurs that an extraordinary degree of precaution should be observed in all cases. Not only should donors and patients be properly typed by well-trained pathologists, but the matching of the two bloods should be insisted upon at all times, just before the transfusion. It only takes a few minutes, and it often saves a life.

That certain proteids contained in the donor's serum should influence the patient receiving it seems very plausible. However, I do not think that such anaphylaxis should be sufficient to cause death—merely reactions more or less severe—but invariably ending in cure.

In regard to using extravasated blood found in the abdomen in a case of concealed hemorrhage, the only blood to be considered is one coming from uncontaminated organs (tear of the liver or spleen, slipping of a ligature after a clean abdominal operation, etc.). As regards the blood found in the abdomen after a tear of the stomach or bowels, I would certainly not use it, as the peritoneum is already potentially infected and using this blood would certainly increase the danger to the patient. I would also not use the blood found after a ruptured extra-uterine pregnancy, or a rupture of the uterus during labor.

I have not used the De Lee apparatus as such, although I have used similar contrivances of my own invention. But while I would succeed in one case I would utterly fail in the next from some unexpected clotting in the syringe, in the tubing, or needles. I understand that in some clinics they use the multiple syringe method with success, filling up in rotation a certain number of 10 or 20 cc. Luer syringes and transferring them quickly to the patient. This requires a number of well-trained assistants that one cannot always have. I have had no experience with this method.

To transfuse blood into an infant's fontanelle is quite easy. The blood is generally taken from the mother or the father. A syringe full of blood—about 10 cc. in a warm, well-citrated syringe—is injected into the anterior fontanelle, properly disinfected with tincture of iodine. The needle used has a short bevel beak. There is a little stopper on the needle, about one centimeter from the point, to allow the needle to plunge into the superior longitudinal sinus, but preventing the needle from entering the brain tissue.

"To you affectionate children will look for the welfare of their parents; to you the anxious parent will turn for the rescue of his child; and on you the fond husband will depend for all that is dear to him in the hour of danger; to you, perhaps, may be confided the lives of numerous men led to the field of battles, or marched through unwholesome countries; to you the health and efficiency of crews destined to long and perilous navigation may be entrusted; on you the public eye is to be bent in days of plague and pestilence, for who shall now say that from such visitations even our happy climate may be free. And under all these circumstances you must be ready to give an account of what has been done, not only to those who are eagerly collected around you, but to a much more troublesome enquirer within."

Clinical Notes and Case Reports

OSTEO-ARTHRITIS OF MARIE

REPORT OF AN UNUSUAL CASE

By A. E. BANKS, M. D., *San Diego*

The case report following is submitted as an example of failure to appreciate true values in history and physical findings, whereby pathogenesis was improperly interpreted and ante-mortem diagnosis prevented. Needless to say chagrin was my constant companion during months of attendance.

Patient, a man of 43, first seen twelve years ago in good health. Has resided in Panama for ten years, from which place he came direct to San Diego, arriving February 26, 1924.

History February 27, 1924—Up to one year ago in good health. Immediately following dinner twelve months ago, "knees gave way, due to pain in joints, and fell down." Symptoms disappeared, but were repeated in three days, since when he has suffered recurrent pain—in knees and ankles principally—though there has been pain in other joints at times. Pain is lightning-like. During the initial symptoms the general health seemed good.

In April, 1924, having become much worse, he consulted Herrick at the Herrick Clinic, Panama. Also seen by Briscoe, James, and Reeder. Reeder performed tonsillectomy. Later the patient consulted Connor at the Ancon Hospital. Their diagnosis was infectious polyarthritis.

An intermittent diarrhea has been persistent since the beginning of the other symptoms. The affected joints, principally the knees and ankles, have been constantly swollen for months. Redness has not been noted. Pain ameliorated during increased swelling. Clubbed-fingers has been noted for most of the time included in this illness (hypertrophic pulmonary osteo-arthritis), though definite time of first appearance not obtainable.

For two years patient has run a bathing establishment at Panama, during which time he wore a bathing-suit more or less constantly.

Status Praesens—He has practically constant pain in most of the joints, but particularly in the knees, with acute exacerbations. Has been taking codein $\frac{1}{2}$ grain with phenacetin 5 grains prn. for a long period, and has lost fourteen pounds during the past year.

Examination—Patient emaciated, facies anxious. Gait hesitant, and evidencing severe pain on joint motion. Fingers of both hands clubbed. Blue line on gum margins. Lips slightly cyanotic. Left knee shows large amount of fluid, slightly crepitant in motion. Right knee has fluid, but less in amount. Tibial ridges roughened and exquisitely tender, as is practically the whole shaft—both sides. Epitrochlears and other superficial lymphatics enlarged, but not tender. Muscular atrophy of the quadriceps group, reflexes hard to elicit, due to tenderness, but probably exaggerated. Chest and abdomen negative. Head, eyes, throat, ears and nose negative; also urogenital system. X-ray (Weiskotten) of affected joints negative for bone changes.

Laboratory Reports by H. A. Thompson—Blood: Reds, 5,126,000; whites, 19,400; polys, 86 per cent. Wassermann blood, negative; spinal fluid, negative; urine and stools, negative; joint fluid, negative; blood cultures, negative.

Mouth showed evidences of severe infection and one abscessed root. (All mouth pathology eradicated by Dr. Care over period of weeks.)

Temperature varies between normal and 102.4 over a period of three weeks; at times (as March 4) running subnormal. Repeated stool cultures finally gave a staph. strep. mixture, from which Dr. Thompson made an autogenous vaccine. It was given with no apparent results.

There being no improvement, in spite of effective treatment of the only discovered source of focal infection (mouth), he was sensitized to horse serum and later

given large dose. Results were encouraging. Swelling subsided in joints and never recurred to a marked extent. Pain, however, recurred the same as originally.

On the theory that negative Wassermann might be unreliable, salvarsan was exhibited freely. No results.

Consultation with Redelings and Frank Carter did not develop new findings.

On June 14, wife found him unable to move his right arm, unable to speak, and with mental confusion. Fifteen minutes later I saw him with Emil Black, and while complaining of numbness and tingling in right upper extremity, motor function was perfect. Speech was slightly impaired. No facial flattening. Speech later cleared up.

Two small ecchymosed spots on margins of tongue indicated that there had been some spasm prior to discovery of condition by his wife.

On June 15, he was referred to Herbert C. Moffitt at

San Francisco who had him under observation for one week, and reported no new findings.

All consultants agreed to some infectious agency as the most likely cause for his joint symptoms. To quote from Moffitt's report-letter: "The distinct clubbing of the fingers, the occasional temperature and the leucocytosis would, however, make some type of infection most probable, as would the course of the disease." On the theory that meningococcic infection might be the ultimate cause, he recommended emetin, which was administered.

Thereafter we exhibited purely as an experiment and because of flat failure to obtain definite evidence of the true cause, both mercurochrome and gentian violet. Results, nil, except to the feelings of the writer.

The aphasia attack was repeated several times, each one, however, being milder than the first. In September he complained of visual difficulty. Hosmer reported eye-grounds normal. Following consultation with Stealey, roentgenogram was made of thorax which at this time evidenced percussion flatness over right upper lobe. Lyell Kinney reported as follows: "There is an oval tumor 5.0 by 6.0 cms. in diameter lying approximately in the center of the upper right lobe, apparently embracing the distribution of the upper right bronchus. The tumor is apparently completely surrounded by healthy lung. It moves with respiration, and it apparently does not encroach upon the mediastinum. The probabilities as to diagnosis are first, chronic abscess; second, a cyst; third, a metastatic tumor."

I did an exploratory puncture and obtained caseous material from the tumor, which was interpreted by the laboratory as being probably an old tuberculosis.

Removal of the lung tumor was considered. The patient refused. Later, events proved this was a happy decision.

Shortly after this visual acuity diminished rapidly, and within a few weeks blindness was complete.

The patient died March 25, 1925.

Necropsy by H. A. Thompson—Subject greatly emaciated. No evident pathology except in upper lobe of right lung and left cerebral hemisphere immediately posterior to fissure of Rolando, where tumors were present, that in the lung being about size of lemon, the cerebral about size of walnut. The center of lung tumor was broken down. The brain tumor did not impinge on the cortex. Sections showed the tissue of both tumors to be carcinoma.

The conditions thought of in attempts to arrive at a diagnosis were particularly echinococcus cyst, meningococcus infection (latent), tubercular focus, peri-arteritis nodosa, syphilis, lung abscess, and some undetermined tropical infection.

The x-ray of chest was interpreted by Kinney, Ruggles, Moffitt, and myself as indicating non-malignancy. To quote again from a letter from Moffitt, in discussion of x-ray films which Kinney had taken to San Francisco to exhibit to our consultants: "As both you and I have thought right along, the course of the disease and the leucocytosis speak pretty strongly for an infection rather than malignant disease, and for a pyogenic rather than a tubercular infection."

Conclusion—Osteo-arthritis dependent on malignancy, not infection, is something to be kept in mind.

Note—All of which demonstrates again the wisdom of Hippocrates when he aphorized to the effect that "Experience is fallacious and judgment difficult."—EDITOR.

The Use of Alcohol in Medical Practice—It is the opinion of Roger I. Lee, Boston (*Journal A. M. A.*), that alcohol is of no benefit as a stimulant in the acute infections. It is possible that alcohol may have some indirect beneficial effect on the metabolism, particularly with regard to fluids; but that does not seem to have been demonstrated clinically as yet. It is only in very exceptional cases that alcohol has any direct value as a food. Alcohol is beneficial in a wide variety of conditions on account of its pharmacologic effect in the production of euphoria. Its benefit is probably never directly life-saving. In order to produce this effect, small doses of alcohol are probably sufficient. Lee says that alcohol should not be employed as a routine and should be employed only in individual cases in which the indications for its use are clear. When the purpose of the administration of the drug is kept in mind, there would be no more objection to the use of alcohol than to the use of opium or its derivatives, but the difficulties in the formation of habit are easily avoided when the treatment is individualized and the drug is administered on clear indications. There seems to be some evidence that in occasional cases the administration of alcohol to the state of mild but obvious intoxication may be beneficial. However, the ordinary indication for the use of alcohol is the creation of mild euphoria. The occasional cardiac patient with a large heart that no longer responds satisfactorily to digitalis and that hovers between compensation and decompensation with a variable amount of dyspnea often finds more comfort from alcohol judiciously given in moderate doses than from opiates, which are better reserved for a future period. In the sometimes inevitable discomforts of old age, as well as in the more sharply definite ailments of arteriosclerosis, alcohol occupies a high place in Lee's regard. Of course, alcohol does not in the slightest remedy the underlying condition. Its uses is entirely directed against the symptoms of the sensation of ill-being. It may even be true that alcohol, even in small doses, may somewhat accelerate a progressive condition. However, if alcohol will enable the patient to eat more and to sleep better, not to mention to give freedom from bodily miseries, it would seem likely that the progressing process in such cases is generally not accelerated by the use of alcohol.

EDITORIALS

M. O. R. C.

Members of County and State Medical Societies who are in acceptable health, and who do not fully inform themselves of the opportunities connected with the formation of the Medical Officers' Reserve Corps, are not only neglecting civic responsibilities and privileges *but intelligent self-interest as well*. The chances are that lack of information fully explains why only 490 of the 1600 medical officers wanted from California; 7 of the 75 wanted from Nevada, and 73 of the 85 wanted from Utah have been commissioned at this writing.

If our members could all have the enlightenment this editor recently obtained from two conferences with Colonel Edward L. Munson, Surgeon Ninth Corps Area, including our Western States, published more fully on page 1424 of this issue, that distinguished doctor would have more enquiries and applications for commissions within one week than he would know what to do with. This M. O. R. C. that so few of us know about is something quite distinctly worth while for every able-bodied doctor, whether considered from the angle of public service or self-interest. It is a *permanent* organization. A permanent mobilizing of the medical forces of our country to meet any and all classes of possible emergencies. The duties are less than nominal, and the opportunities and privileges are appealing. When the quota is filled, it is filled. And, in case of need, those holding commissions in the Medical Officers Reserve Corps will be the first assigned to active duty *at the rank they then hold*. Others, of course, *will be drafted and take what is left*. State and County Medical Associations have endorsed this movement and are sponsoring it. Every member should at least investigate this opportunity for public service *and personal protection*. Address the Surgeon Ninth Corps Area, Presidio, San Francisco, California.

ABSORPTION OF DRUGS FROM THE NASAL AND ORAL MUCOSAE

The absorption of volatile agents from the nasal and oral mucosae is well known, but it is frequently denied for or unsuspected with the non-volatile. It is a common laboratory experiment to demonstrate the toxic and fatal effects of nicotine by placing a drop of the alkaloid on the gums of an animal. The effects of tobacco-chewing in the novice or of chewing a cigar stump are too well known to require description. Occasionally, the physician is disturbed by the sudden or gradual development of alarming symptoms, and even collapse and death, from the local application of cocaine and other anesthetics in these regions. This means that probably the cocaine has been absorbed and caused systemic

poisoning. Anaphylactic sensitization from the nose and absorption of caffeine from cigarettes have also been reported. Nitroglycerine is commonly administered by application to the tongue. Its absorption by this method and by gastric administration was discussed in these columns some time ago. A knowledge of the scope and quantity of nasal and oral absorption of non-volatile drugs is desirable, for it might be of toxicologic and therapeutic importance. This has recently been obtained for certain hypnotic and coal tar derivatives by Planelles of the Munich Pharmacological Institute.

Planelles first demonstrated it in vitro experiments that smoke collected from cigarettes impregnated with antipyrin, barbitol, salicylic acid, and acetylsalicylic acid, invariably contained all the drugs, including unchanged acetylsalicylic acid. He then smoked such cigarettes himself, allowing the smoke to come in contact with the oral and nasal mucosae and avoiding swallowing and deep inhalation (alveolar absorption) as much as possible. At the same time the urinary excretion of the drugs was studied. Under these conditions, Planelles demonstrated qualitatively the presence of antipyrin, barbitol, salicylate and acetylsalicylic acid, as salicylate, in the urine. A quantitative study of barbitol excretion showed that about 20 per cent of a 0.3 gm. quantity of barbitol placed into and smoked as a cigarette appeared in the urine. Smoking a 0.5 gm. quantity of barbitol caused the appearance of the drug in the urine at the end of 10 minutes, while after swallowing the same quantity, the time of appearance was 20 minutes. After smoking, the drug disappeared from the urine at the end of 30 minutes, and at the end of 60 minutes when it was swallowed. According to Planelles, the dermal absorption of barbitol is about 20 per cent. If this is true, certainly the nasal and oral surfaces compare favorably with the skin, and from Planelles' results the absorption would be faster and completed sooner from the nose and mouth than from the gastro-intestinal tract. Confirmation of Planelles' results is desirable, but it is suggestive that prompter hypnotic effects of barbitol might be secured by simply holding the drug in the mouth instead of swallowing it, for the onset of the drug's action is notoriously slow, whatever the cause.

In any case, the results of Planelles, and from what has been said, leave no doubt that a variety of volatile and non-volatile agents, including protein among the latter, can be absorbed from the oral and nasal mucosae. It is well to bear this in mind at least in connection with the possible toxicity of local anesthetics, especially with cocaine which is notorious for its irregular absorption. Then there are certain antiseptics (toxic dyes and other kinds) which are being used in the nose and mouth, let alone systemic disturbances and possible toxicity, especially in children, from the indiscriminate use of drugged lozenges, nasal sprays, and a variety of other preparations of the patent medicine type used by the laity.

Planelles, J.: Arch. exp. Path. Pharm., 1924, 104:272.
"Resorption dampfförmiger Medikamente durch die Nasen—Rachenschleimhaut."

UTAH HOLDS A GREAT MEDICAL CONVENTION

Doctor Walter C. Alvarez of San Francisco has just returned from the annual meeting of the Utah Medical Association, which lasted for a whole week, and writes us as follows:

Just a note to congratulate you on a fine number of CALIFORNIA AND WESTERN MEDICINE, and on your success in getting so many good things boiled down and put into such a small space.

"I have just gotten back from the meeting in Salt Lake City which was a great success, and I think followed out an excellent idea. For the first time in my life I saw about one hundred doctors attend meetings faithfully from 8 a. m. to 9:30 p. m., and from Monday morning to Saturday noon. I wondered if perhaps there was a little Scotch blood in some of them to help out because they had each paid \$10 for the course. Perhaps the best part of the scheme was that they had men from other states, all teachers of medicine and surgery, and distance always lends enchantment. They were wise, however, in asking these men to give practical talks on common, everyday subjects. It was so interesting that I attended from early morning till late evening. Perhaps some time a meeting like that would go well in California. Credit must be given to Kahn, Critchlow, and Rich, who are splendid fellows and who worked the thing up and prepared for it a year ago."

The minutes of the House of Delegates and proceedings in general of this intelligently conducted and highly successful medical meeting will be found elsewhere in this issue of CALIFORNIA AND WESTERN MEDICINE. They are worthy of the careful perusal of every physician interested in the welfare of his profession, and particularly in the advancement of the cause of better health for everybody. The days of the stereotyped soporific conventional meeting of medical organizations are over, at least in centers where physicians assume their duties and play their parts in organizations, as they do in personal affairs.

The time is here when the physician who wants to get his message, whether written or spoken, over must deliver it in an attractive and appealing form. An increasing number of individuals in our profession, as well as outstanding organizations of physicians, are moving ahead with rapid strides, not so much because of their superior intelligence, but because they pay the same careful attention to their literary efforts that they do to their technique in the operating room.

If Utah, with its 354 physicians, can make the remarkable showing that they undoubtedly did make at their recent session, the California Medical Association with its more than 4000 members ought to make its annual meetings a source of profit and pleasure, not only to physicians, but to every citizen of this state.

MEDICAL AND SURGICAL "CONVERSAZIONI"

This innovation, introduced in the September issue of CALIFORNIA AND WESTERN MEDICINE, has produced such an extensive and agreeably surprising reaction that the department will be continued. This is a sort of open forum, as it were, to discuss pertinent problems of "*Bedside Medicine for Bedside Doctors*." (What would you think of that for a title instead of "Conversazioni"?)

We desire to give the widest opportunity to our

readers to discuss various subjects. The following six subjects are now being prepared for discussion. If you are interested in supplying us with a discussion of not over five hundred words on any of these subjects, please notify the editor.

1. A Brief of the Evidence that Justifies a Diagnosis of Infantile Paralysis.
2. What are the Essential Indications for Caesarean Section?
3. Under What Conditions, if Any, Is Appendicectomy Justifiable?
4. Do We Need More Than One Class of Nurses? If So, What Shall Distinguish Them—In Education, Duties, and Responsibilities?
5. Should Drug Addiction be a Reportable Disease.
6. What Constitutes the Minimum Evidence Warranting a Positive Diagnosis of Diabetes Mellitus?

The Control of Rickets—That animals can be protected against rickets by the use of cod-liver oil and ultra-violet light is an established fact. It has also been clearly shown that cod-liver oil and sunlight exert a great influence in the cure of rickets. Whether these measures are sufficient to prevent rickets in infants in a community has been made a problem of investigation in New Haven. Martha M. Eliot, New Haven, Conn. (Journal A. M. A.), describes the plan of the study and offers a preliminary discussion of the results. The demonstration was started in October, 1923, for a three-year period by the United States Children's Bureau in conjunction with the pediatric department of the Yale School of Medicine and with the active co-operation of the local health organizations. A district of the city was selected having a population of approximately 13,500, one-third of which were negroes, and two-thirds a mixed population composed of Italians, Irish, Polish, and Americans. The office of the demonstration is known in New Haven as the "Children's Bureau." The staff consists of three physicians, three public health nurses, two social investigators, a roentgen ray technician, and a secretary. The main problem of the investigation was to show whether rickets could be prevented in a community by the intensive use of cod-liver oil and sunlight. The infants born within the selected district during the first two years of the study are examined and started on cod-liver oil and sun baths, if possible, before the end of the first month of life. They are brought to the Children's Bureau once a month for physical and roentgen-ray examinations in order that rickets may be discovered as early as possible, and intensive treatment instituted if necessary. The nurses visit the homes frequently to see whether the instructions are being carried out. These investigations have shown that a slight degree of early rickets is well nigh universal in our climate and in our state of society. The very intimate association of rickets with growth, its early appearance regardless of season, and its universality raise the question whether this slight degree of rickets must not be considered normal. That rickets is intimately associated with growth is well known, and that it should appear at the time when most active growth is taking place, namely, the first four months of life, is not extraordinary. The rate of growth of the infant influences the early development of the disease. Large, rapidly growing breast-fed infants and very fat infants uniformly show definite evidence of rickets. It is an uncommon thing to find a healthy, vigorous breast-fed infant who does not show rickets by roentgen-ray examination. Premature babies, who grow exceedingly rapid, are notoriously rachitic. Malnourished infants frequently show small, slender bones with little or no rachitic change. If any two groups of infants show the need of early anti-rachitic treatment more than others, they are the large, rapidly growing breast-fed infants and premature babies.

There is too much birth control and not enough control of them after they are born.—San Francisco Chronicle.

- The MONTH with the EDITOR -

Notes, reflections, extracts from correspondence, comment upon medical and health news in both the scientific and public press, briefs of sorts from here, there and everywhere.

"THE SURGEONS AND PHYSICIANS OF THE WORLD know practically nothing about how to make an old man young," said Doctor Emmett Rixford upon his return recently from Europe. He endorsed the statement of a colleague who said, in effect, that "It takes more than three kinds of monkeys to make a young man out of an oldster." The three who are usually active in the effort—for a price—are, the patient who is operated on, the surgeon who operates, and the monkey that is the victim.

Goats might well be substituted for monkeys, and the statement would still be true. But goat glands are cheaper and profits greater. The sale of goats' testicles is said to be lucrative business for slaughterhouses.

"BY THIS YOU MAY KNOW THEM"—"A famous British surgeon visiting this country," says the San Francisco Examiner editorially, "was asked if he had brought over any new secrets of his art."

"He said, 'Our profession is international. When we find a new way to conquer the ailments of mankind they are immediately communicated to the whole world.'"

"So it is in all science. Those who are trying to make things better for the whole human race have no secrets from each other. *By this you may know them.*"

We do not know who this British surgeon referred to was, but it wasn't Hadden nor those of his ilk who frequently occupy "news" space.

WE ARE INDEBTED TO DOCTOR WILLARD J. STONE of Pasadena for a copy of the outstandingly able Baccalaureate Address delivered by Rev. Lloyd C. Douglas at the University of Michigan commencement exercises. Extracts from this address are used elsewhere in this issue.

"OVER ONE HUNDRED MILLION PEOPLE in the United States escaped being run over by automobiles last year, several of them having also escaped the year before."—Life.

California, Nevada, and Utah Doctors Publish Elsewhere:

[Note—Members of the California, Nevada, and Utah Medical Associations are invited to supply the editor with reprints or marked copies of magazines containing their articles or very brief abstracts. All that we receive will be noted regularly in this space.—Editor.]

—FRANK HINMAN OF SAN FRANCISCO AND ALEXANDER B. HELPER OF SEATTLE (Archives of Surgery, October, 1925) discuss "Experimental Hydronephrosis."

—LEONARD W. ELY OF SAN FRANCISCO (Archives of Surgery, October, 1925) reports a case of Sprengel's deformity.

—M. S. WOOLF, SAN FRANCISCO (Archives of Dermatology and Syphilology, October, 1925) writes on "Leukonychia Striata."

—EDWARD N. TWITCHELL, SAN FRANCISCO (Pacific Coast Journal of Nursing, October, 1925) takes "Psychiatric Training in Nursing Curricula" as his subject. Twitchell proposes to use bedside teaching for nurses.

—WALTER C. ALVAREZ, SAN FRANCISCO, discusses "Digestibility versus Roughage and Vitamins" in "Baking Technology" of September 15. The magazine is the "house organ" of the American Institute of Baking:

"There is little need for worrying at any time about the vitamins in the diet of an average middle-class American," believes Alvarez. "He will probably get all that he needs even on a smooth diet; and so far as I know, there is as yet no evidence that a superfluity of vitamins makes a man any more healthy than he is when he has just enough for his needs."

—In another article (Journal A. M. A., October 3, 1925) Alvarez writes on "Reverse Peristalsis in the Bowel, a Precursor of Vomiting."

—HAROLD K. FABER OF SAN FRANCISCO (American Journal of Diseases of Children) discusses "Variability in Weight for Height in Children of School Age." His most important conclusion is that:

"Variability in weight for height, in the directions of both underweight and overweight, increases with age in both sexes. These differences and variations in variability are too great to be disregarded in favor of a single standard of variation, such as is now in general use."

—J. W. ROBERTSON, V. H. PODSTAT, C. W. MACK, AND JEWEL FAY have issued an instructive pamphlet on "Occupational Therapy," as practiced at Livermore Sanitarium. The excellent, ethical, and all inclusive scientific treatment and care of the mentally ill as it is being carried out at Livermore Sanitarium is doing much to popularize institutions for this big service, as has long since been done for hospitals for the care of physical ills.

The Book Analysis Service of CALIFORNIA AND WESTERN MEDICINE is being made more valuable because several doctors are *voluntarily* sending in reviews of books that come to their notice.

More doctors—and others also—rely upon this service than book publishers realize. Our correspondence upon this subject is illuminating and encouraging.

Careful, fair reviews of books, solely in the interests of our readers, are welcome from any doctor or other reader. Obviously, such effort is a work of love, because only the editor and his councilors may know who writes a review.

Any review that is published represents the magazine, and not the opinion of any one person.

More and more correspondence about books is invited.

A "NEW" HEALTH SLOGAN—If it were not for the fine dust which we breathe and the stagnant water which we drink, Adam's sons would live for ten centuries.—Mohammed, in the Koran.

DOCTOR HAROLD W. WRIGHT, formerly of San Francisco, is now consulting neuro-psychiatrist to the Department of Welfare of Pennsylvania. Doctor Wright feels that the experience he is gaining in initiating traveling diagnostic clinics will be of use in our effort to provide better health for all people.

According to the Public Press:

—The following doctors were to be tried before the Board of Medical Examiners for the alleged offenses set opposite their names:

"Dr. Herbert E. Bogue, Los Angeles, charged with violation of the narcotic laws; Dr. Rebecca E. Dorsey, Los Angeles, 'goat gland specialist,' charged with illegal advertising; Dr. Edward O. Hanlon, Los Angeles, narcotic charge; Dr. Toshio Ichioka, Los Angeles, illegal advertising; Dr. Franklin E. Kerr, Orange County, convicted of sending poison candy through the mails to his wife, and Dr. Robert Renwick, Los Angeles, aiding and abetting an unlicensed practitioner."

An interesting group of alleged offenses, particularly the charge that a "goat gland specialist" can be guilty of illegal advertising. What on earth could she say in her advertisements that is not frequently featured as "news"? The legal fences around "doctors" are so low and ramshackle that our board will have to keep very busy keeping poachers out. However, do the best you can, fellows, we are with you.

—A "nutrition expert," in speeding along the "royal road to health," has discovered the "wiggles" is a terrible children's disease, and that it is caused by too much tea or coffee.

This "expert," according to newspaper display, "warns"

the school children that "the wiggles will get you if you don't watch out."

Now that is "health education" as she is!!!

⁶⁶THE practitioners of the highly profitable pseudoscience of 'Fakopsychanalysis,' predicts the San Francisco Chronicle editorially, "are folding their tents and seeking new fields where one may get a fat living without working for it. 'To Let' signs are adorning the doors of offices where personality doctors formerly diagnosed the mysterious causes of laziness, incapacity, and general discontent.

"These cure-all quacks are on their way, making room for the next strange madness that lays hold upon idle minds always ready to be exploited by fakers."

G. B. S., the well-known British satirist who apparently gets enjoyment out of "stirring the animals," is again after the medicos. He prods rather ruthlessly and often stupidly, but after all he does good. He is getting well along in years, and it is safe to prophesy that he will call for one of the members of that "self-disgraced trade union, the British Medical Council," as he calls it, at no far distant date.

Some of the little G. B. S. imitators in our country unfortunately are much younger.

"CHIROTHESIAN FOUND NOT GUILTY—M. T. Larkin, Los Angeles, who was arrested on a charge of practicing medicine without a license, was found not guilty after a three-day jury trial. Albert Carter, special agent for the State Board of Medical Examiners, cites this case as an example of the handicap of prosecuting cases with inexperienced prosecutors. The evidence showed that Larkin treated paralysis, tumors, rheumatism, and kidney disease. Larkin contended he had the right to do such things in accordance with the tenets of the Chirothesian Church, of which he is a member."

Thus we have another of the 57 varieties. Soon they will be wanting their own board to license and control themselves.

When they do they may profit by the experiences of the chiro, and not make their law so tight that they cannot get in themselves.

Judge—Do you wish to marry again if you receive a divorce?

Rastus—Ah should say not! Ah withdraws from circulation.

DOCTOR MARIANA BERTOLA, President Federated Women's Clubs of California, was recently the guest of honor at a luncheon, with the San Francisco Clubs as hostesses. It was a remarkable testimonial of the esteem and affection in which Doctor Bertola is held by the great organization she is to head for the next two years.

The scene was an impressive one to those accustomed to observe humanity in mass movements. The some four hundred women who attended the luncheon were from all of Northern and Central California, and they were in earnest—justly so—in the beautiful tributes they paid to the guest of honor. The "lone man" guest was the most impressed person present—impressed with the immense power for good inherent in these serious-minded members of our families who are rapidly forming themselves into all that their name—Federation—implies; impressed with the facility and aptness with which the numerous speakers delivered their telling messages, and with the lively discriminating interest with which these messages were received.

The permanent message the "lone man" guest carried away with him was that mothers have moved their conference tables from individual meditation over the kitchen table to the forum tables of vast conference halls.

Another permanent impression was that these mothers, wives, and sisters loved their president, Mariana Bertola, another evidence of wisdom that will be seconded and applauded by every physician in California.

With Medical Editors:

—Long Island Medical Journal plans to run a series of articles written in "textbook style." The editor says:

"While textbook articles in medical journals are ap-

proved by most doctors, yet some medical leaders do not favor them because doctors can find the information in textbooks. Our reply is that an author of a textbook is seldom willing to state a simple, positive line of treatment which a family doctor can recommend to his patient, and yet that same specialist is perfectly willing to outline a dogmatic line of treatment to a doctor with whom he converses in a friendly way."

—The editor of the Boston Medical and Surgical Journal, June, compliments BETTER HEALTH magazine, by reproducing one of its editorials.

—In a lengthy editorial on "The Evolution of the Doctor" (Journal of the Kansas Medical Society) it is stated that:

"For the greater part of a century the family doctor has been passing, not through a process of decadence, but a process of evolution—a process of evolution dependent upon conditions over which he had little if any control, and with which the medical profession as a whole had nothing to do."

—"The general practitioner, in the old sense, is indeed gone, but not so the trusted friend and family adviser," states the editor of the Rhode Island Medical Journal. "He still exists, usually in the person of a medical man, sometimes a surgeon and sometimes a rather questionable combination of the two, but still he remains the father confessor in matters of health, the clearing house for family illness."

—"IF CRIME CONTINUES UNCHECKED AND UNPUNISHED, with murder excusable on the specious pleas of 'glands' and 'insanity,' the country cannot survive. Never was there more pathetic demonstration of 'A little learning is a dangerous thing' than the fashion in which justice is prostituted to meet the demand of sentimentalists and the hawking of learned phrases in the mouths of comparatively ignorant laymen."—Editorial Illinois Medical Journal.

—"A VERY LARGE PERCENTAGE of the regular medical profession is both progressive and ethical, but there is an element within our profession that represents quackery and dishonesty which little effort on the part of the profession has been put forth to abolish. *Some of the quackery and deception practiced by supposedly reputable members of the medical profession is of that refined and polished type that is hard to detect by the average observer.* Some of it is blatant and crooked, with no attempt to gloss it over, and our profession suffers by harboring within its ranks these men who disgrace us."—Editorial Journal Indiana Medical Association.

STATISTICS may demonstrate that ox-carts were safer than motor-cars are; but we are through with ox-carts, and are not going back to them, though the casualties on our streets are multiplied by ten—which Heaven forbid!—Rev. Lloyd C. Douglas, Michigan Alumnus.

Fake Oil Stock Promoters and fly-by-night salesmen of other classes have found such "good pickings" among physicians that a growing group of "twilight zoners" of our own profession have entered the skin-game field with a variety of schemes calculated to separate credulous doctors from their hard-earned savings.

Some of these medical sharpers have jail records, and almost without exception their records as physicians and citizens are shady or dirty.

Like others of their ilk they have caught on to the fact that a paper organization with a high-sounding name is an asset. An attractive policy expressed in ambiguous platitudes also helps.

Several letters inquiring about some of these "movements" have been received from members recently. One of the most active who is sending out most alluring letters has a "newspaper morgue" record that would make a billy goat whose "glands" had been used by rejuvenators blush for shame.

"ANHEDONIA" is "coming in" fast. The word is not particularly new, but its definition, once limited to "absence of pleasure from the performance of acts which would ordinarily be pleasurable," has expanded to include "Americanitis," neurasthenia, and many more allied conditions.

We now have books on the "subject," one of which, by

Abraham Myerson, is more than passably interesting and will be found useful reading by physicians.

SOMEONE MUST HAVE PAWNED OFF A PHONY mailing list on a hernia cure "specialist" recently. Many people who never had a rupture or who have long since been cured by operation, are being deluged and importuned by one of those "wise birds" of New York who can fit your truss by mail, to buy his truss and be cured.

This "doctor" proposes to extend thousands of lives by fitting a truss by mail for a fee. Not only that, but—for a fee—he will also supply by mail an ointment that will make the tissues so strong that the next rupture must perforce break through elsewhere.

There is significance in the fact that non-medical people send "literature" of this quality to a medical editor and invite comment.

Doctor Murdered When Answering a Fake Call! Baby of Murdered Nurse Discovered!—Headlines like these are becoming all too frequent. It has been exceptional when the doctor and his "black bag" and nurses in uniform were interfered with in their errands of mercy. Is this form of murder and gangster a new product? Is the time coming when these servants of suffering humanity must add an automatic to their equipment?

THE FAMILY DOCTOR AIN'T WHAT HE USED TO BE, according to Bill Bailly (San Francisco Bulletin). Of course not, Bill, and neither are journalists, farmers, lawyers, laborers, any others who make a living—we hope—out of *service*. Bill's chief complaint is that during the old days "a fellow could get sick any time, day or night, and old Doctor Jones would come, but now can a person become ill any time he feels like it? One should say not?"

One of our readers suggests that we ask Bill to try to get a plumber, electrician, or any other kind of skilled worker any time he thinks he needs him, and he will find that they, too, take certain times for recreation and sleep.

TAKING FOR HIS TEXT the "me too" statements by Doctor Copeland (Collier's) about the alleged disappearance of the family doctor, the editor of the San Francisco Chronicle says, among other things:

"We may gain in health, but we shall lose a great deal in sentiment when the old family doctor passes completely out of the scheme of things and a younger, brisker practitioner of preventive medicine has taken his place."

Don't worry, brother editor, the family doctor is not going. He may change as those of other vocations change, but he will still correlate new facts and apply them as of yore. He will become more able scientifically without losing his pristine art. He will pick out the rare kernels in the vast chaff of the "new psychology" and serve them clean at the bedside and elsewhere without blowing the smut and chaff all over the home. He will do all of these things and others, *but he is not going*. Quite the contrary. There are more family doctors now than ever before—well over 100,000 of them in our country. There are worthy specialists, too. Many of them, and they—at least those worth while—sustain the hand of the new family physician—personal health counselor, as President Vincent of the Rockefeller Foundation calls him—rather than detract from his sphere.

There is nothing, except the wish that is father to the thought, to indicate that the personal health physician is disappearing.

From Our Correspondents:

—DUDLEY SMITH, M. D. (Oakland and San Francisco)—Regarding "Medical and Surgical Conversaciones," I believe these discussions will be very popular and very valuable, and that you are wise to continue to devote space to them.

—WILLA A. CAMERON, M. D. (Keswick, Iowa)—Yes, indeed, I should like more "Conversaciones" of the type found in the September issue of CALIFORNIA AND WESTERN MEDICINE.

—EDWARD C. HALLEY, M. D. (Fresno)—We feel that

CALIFORNIA AND WESTERN MEDICINE has hit upon something very practical in "Conversaciones," instituted in the September issue. It is comforting indeed to learn that the well-known contributors to the initial article, when asked for a definite and concise opinion, expressed themselves so in harmony regarding gall-bladder surgery. We did not surmise that there was such general agreement in dealing with gall-bladder pathology.

I shall be willing to take any part in the discussion that you may deem me qualified to handle.

—C. B. ALEXANDER, M. D. (Alhambra, Calif.)—I enjoyed reading the "Conversaciones" by invited authors very much. It certainly is a new and direct way of getting the meat in the coconut. Here is hoping you continue it. Would enjoy joining in "Conversaciones" on Surgery at any time.

YOU can make more money being a quack, a petti-fogger, a spiritualistic medium, a phrenologist, a palmist, an itinerant tent-evangelist, a patent-medicine peddler, or a plain second-story man, than in any honest, self-respecting vocation.—Rev. Lloyd C. Douglas, Michigan Alumnus.

Treatment of Bronchial Asthma—This paper by Albert H. Rowe, Oakland, Calif. (Journal A. M. A., June 20, 1925), is based on 234 cases of bronchial asthma in which the patients have co-operated satisfactorily in their treatment. The occurrence of allergy in antecedents has been carefully noted, 56.4 per cent of the patients showing a positive family history. Angioneurotic edema occurred only twice. Ninety-one per cent of the patients gave one or more positive skin reactions. Rowe feels that this high percentage of positive reactions is due to the use of a large number of food, animal emanations and pollen proteins, to the use of orris root in routine testing, and to the use of many miscellaneous proteins in the unusual case. Retesting on several occasions when the asthma remained uncontrolled has revealed many reactions that would have been missed. In this series no positive reactions to bacteria have been recorded. Of the 234 patients, 63.4 per cent had complete or nearly complete relief from treatment; 26.9 per cent had marked relief; 5.5 per cent had slight relief, and 4.2 per cent had no relief, the patient himself or some member of the family being in each instance the judge of the result obtained. Results were satisfactory in approximately 90.3 per cent. The treatment has been guided by the skin reactions. For the control of food sensitization, total exclusion of the offending substance is necessary. Wheat, in Rowe's experience, most frequently gives important food reactions. Many delayed reactions to wheat have also revealed a true sensitization. Eggs, milk, and the cereals other than wheat follow in order of importance. Pollen reactions have occurred in 39.7 per cent of the cases, and nearly all have required pollen desensitization. Positive reactions to one or more animal emanation proteins have occurred in 58.5 per cent. Feather proteins have reacted in 16 per cent of the cases. These proteins have also given many delayed reactions, and successful treatment based on these reactions has often corroborated the indicated sensitization. Orris root gave positive reactions in 10 per cent of the cases. In this series, 169 operations had been performed on 110 patients, with only slight relief of the asthma in a few cases. Rowe's experience is that uncontrolled cases are rarely helped by climatic changes. Epinephrin should be used to control spasmodic attacks, but it is often useless in severe cases. Two or three grain doses of chloral hydrate combined with four or five minimum doses of tincture of hyoscyamus has helped to tide over the patients while the diagnosis is being made and treatment instituted. Iodids in large doses give many asthmatic patients some relief. The burning of niter and stramonium leaves is indicated when it gives relief. Quartz light with vaccine therapy has been found very valuable when bronchitis complicates asthma. Morphin should rarely, if ever, be used even in the most severe attacks, because of its demoralizing effect on the patient. Calcium chlorid and peptone intravenously have been of no value in the control of Rowe's cases of severe asthma.

Medical Economics and Public Health

Gorgas Memorial Institute—Doctor Franklin Martin, chairman of the Gorgas Memorial Board, in a recent letter informs us that the criticism noted on page 1185 of the September issue of CALIFORNIA AND WESTERN MEDICINE regarding the appropriation of the term "Better Health" by the Gorgas Memorial had received the attention of the institute and would hereafter be discontinued.

This evidence of fair dealing is creditable to the Gorgas Memorial people, and pleasing to the physicians of California.

Doctor Martin says, in the closing paragraph of his letter, that "the object of the Memorial is to cultivate co-operation, not only between the medical profession and the laity, but to co-operate with all agencies working for health betterment. I hope the various organizations working toward that end in California will recognize this attitude on our part and pull with us."

"If more Physicians Took the Trouble to Make Thorough Examinations of Their Patients, never failing to examine the chest after the clothing had been completely removed from the upper part of the body and using auscultation, percussion and palpation, which are fundamental to physical diagnosis, there would be fewer failures and many more persons satisfied with the care of their physicians."

"If medicine is to be partitioned off into a series of specialties and cults practiced by men who have learned only one organ of the body or only one system of diagnosing and of treating disease, medicine as a science is bound to fail. No part of the human body can be detached and treated as separate from the organism as a whole."

"Physicians have watched the inroads made on the practice of medicine as a single science. They have noted the attempts of optometrists to parcel off the eye as their particular field; of cosmeticians to assume the right to treat disorders of the skin and to request legislatures to grant them power to remove moles, warts, tumors, and other excrescences; of chiropodists to assign to themselves the complete care of the feet; of chiropractors and osteopaths to make the field of manual manipulation their exclusive purview; and of some of the specialists within the ranks of medicine itself to assign all important functions to the teeth, to the lungs, or to other organs of the body. The time has come to call a halt on geographic warfare within the human body, and to look on it as a 'united states' that will be at least as firmly consolidated as the forty-eight individual constituents of our government."—Morris Fishbein (Journal A. M. A.).

The Loss of Doctor Harry E. Alderson's Services on the Board of Medical Examiners of California, after fourteen years of splendid service, is a loss to the cause of better health for all of our citizens. Anyone at all familiar with the trials and responsibilities of this board and with Doctor Alderson's uncompromising stand in the interests of public welfare will regret the conditions, whatever they may be, which influenced the governor to drop him from the board and substitute a doctor of much less experience in this particular type of work, whatever other accomplishments he may have.

Governor Richardson of California has "drafted" Doctor A. W. Morton to serve on his board charged with the duty of enforcing medical licensure and the enforcement of medical practice laws. *Doctor Morton is a member of the San Francisco County Medical Society.*

We Have Received From Some Unknown a marked copy of an interesting editorial apparently from *Medical Economics* which says, among other interesting things, that:

"Physicians will do well to hearken to the radio, as it broadcasts much medical information and some misinformation to the invisible millions.

"An irregular practitioner," continues the editor, "can go on the air, with a bald advertisement at so many dollars a minute, as was shown in a recent case in court. Healing cults, fantastic practors, faith curists, and all manner of persons who deny the basic truths of science, can have their voice. More than a hundred years have passed since Jenner, and yet there are faddists who are attacking vaccination and airing their views to the wide, wide ether. The publication of such matter as this, whether in the press or on the metered waves, is contrary to an enlightened public policy."

The chief trouble about radio or any other kind of advertising is that some people can't distinguish between promoting a cause and advertising an individual. The County Medical Society broadcasting would lend dignity and value to any health message not possible to obtain when broadcasted by any doctor, however well press agented.

According to the Public Press—The Berkeley Chiropractic College and its president, Percy Purviance, has brought suit to prevent the California Board of Chiropractor Examiners from conducting an examination of the "college."

"Such an investigation, Purviance alleges, would be a violation of the school's rights, if for no other reason than that *no member of the board of examiners was a licensed chiropractor for three years prior to his appointment to the board, as required by law.*"

An interesting point, and judged by previous history of the chiropractic law, one likely to win in the courts. Members of a former chiropractic board were ousted by the courts on the ground that they had not been "legally practicing chiropractic for three years" at the time of their appointment, as required by law. It begins to look as if the chiro had made their law so tight that they cannot get in themselves.

But they are "making hay," as shown by a report that they had recently licensed over 1500 of themselves. Once in, no matter how, there they are. Hurry up, boys, and get in before the illegality of your board is rediscovered.

Our Officials Tell Us that it cost the taxpayers of California from \$237.63 to \$290.32 per patient for care in our state hospitals last year. Assuming that the "shut-ins" had even decent care, these figures are really funny.

But look at this! Presumably, by the same sort of book-keeping, it cost from \$253.71 to \$280.77 per capita to maintain our prisoners. Does this help explain the popularity of prisons?

But look a little further. According to the official figures, it cost \$711.56 to keep a girl in the California Correctional School for girls; \$374.68 per head at the Correctional School of Industry, and \$643.03 per head at the Whittier Reform School.

At the Industrial Home for the Blind the cost was \$394.28, and \$492.02 per inhabitant at the Veterans' Home.

Interesting figures, aren't they?

Why is it cheaper to serve the mentally—and often physically also—ill citizens in "hospitals" than it is to serve criminals and the theoretically reformable in prisons and reformatories?

"Father, forgive them, they know not what they do."

Thank God for Ministers like Lloyd C. Douglas, who, in delivering the Baccalaureate Address at Michigan recently, said among many other important things that:

"When the honest scientist is haled into the witness-box by the irascible majority and is obliged to answer certain queries which it has conceived in stupidity and brought forth in impertinence, and candidly replies, 'We do not know,' the public shouts: 'Aha! Just as we thought! You do not know. Very well. We will go to somebody who does know,' and scurries away to the chiropractor (until very recently the driver of a jitney-bus); and the man with the Abrams machine (who has just retired from the tonsorial profession) and the owner of a neurocalomotor, who, by an examination of a lock of hair, a drop of blood and a certified check, can diagnose any ill to which mortal flesh is prone; and draw from a slot in the device a prescription that will guarantee a lasting cure by Thursday, at the latest. In every

department of life, small men willing to make capital of the public's psychoses; and unsuccessful men, who have tired of being honest at the prevailing price of that commodity, are arrogating to themselves large leadership. They speak with conviction. They never doubt, or wait, or hesitate, or ask the patient to come back next day for a decision. They put their dogmas down on the table with a bang and a growl. The public has been beaddled, mentally, just long enough to like that school of thought."

"No Smallpox was Reported in Rhode Island in 1923, nor during the last half of 1922. During the same period it was prevalent in the neighboring state of Connecticut. Rhode Island is free from this serious and disgusting malady because of the almost universal practice of vaccination in their public schools."

The Processes of Human Selection, according to Warren S. Thompson of Miami University, in a paper read before a meeting of the American Sociological Society and published in a recent issue of the Monthly Labor Review, are probably somewhat less rigorous than they were two thousand years ago because of modern medicine and charity, but if the lower classes, and particularly the defective, benefit most from modern charity, the upper classes benefit most from modern medicine, and probably the unfit thus kept alive do not materially change the relative proportions surviving in these different classes. It is the differential birth rate which changes these proportions, as anyone can readily see who studies mortality and morbidity tables.

Dr. Poo-Poo-Sin, as we will call him, is a Chinese herbalist who advertises extensively in certain newspapers. When the matter of advertising an unlicensed person to engage in illegitimate business was called to the attention of the newspapers by the Board of Medical Examiners, one of the excuses given by one of the papers (and it has also been given in Courts) was that "Dr. Poo-Poo-Sin" was patented or copyrighted by the United States Government, and therefore the illegal practitioner had a legal right to live up to his patented prerogatives. ? ! + —.

Mr. A. B. Bianchi, attorney for the Board of Medical Examiners, has now rendered a decision that ought to effectively settle this stupid claim. He ruled that Section 17 of the Medical Practice Act, as far as applicable for the purposes hereof, is in part as follows:

"Any person . . . who shall in any sign or in an advertisement use the word 'doctor,' the letters or prefix 'Dr.,' the letters 'M. D.,' or any other term or letters indicating or implying that he is a doctor, physician, surgeon or practitioner under the terms of this or any other act, or that he is entitled to practice hereunder or under any other law without having at the time of so doing a valid, unrevoked certificate as provided in this Act, shall be guilty of a misdemeanor and upon conviction thereof shall be punished as designated in this Act."

"The public at large has long associated the use of the word 'doctor,' and the symbols 'Dr.' and 'M. D.' with the practice of medicine. The purpose and object of the statute is to protect that public. In several of the states, the Medical Practice Acts have defined the use of those terms as constituting *ipso facto* the practice of medicine. To protect the public, therefore, it has been deemed advisable to restrain the use of this title and prefix and to compel all those entitled to prefix, or append such letters and titles, to be properly qualified and registered under the law.

"In California the use of the title 'doctor,' or the prefix 'Dr.' or the affix 'M. D.' by one unqualified under the Medical Practice Act has been made a crime. I know of no law which will act as a screen or defense, or which can be used as a screen or defense, for the violation of such a statute, passed for the public safety. If it were possible to hide behind the copyrighting of the word 'doctor,' the prefix 'Dr.' or the affix 'M. D.' in connection with any name, this statute could be violated by everyone in California, thus rendering it entirely nugatory.

"You will remember that in the case of Berry v. Alderson, the defendant sought to hide behind the incorporated name of 'K. C. Bloodless Surgeons,' and neither the Ap-

pellate nor the Supreme Court gave any attention to the contention that the defendant was entitled to use this fictitious name, and it was not held necessary in that case that the evidence show any fraud actually perpetrated on the public.

"I, therefore, advise that the use by anyone in any sign or advertisement of the word 'doctor,' the prefix 'Dr.' or the affix 'M. D.' is a violation of Section 17 of the Medical Practice Act, unless at the time of so doing he is entitled to practice under and by virtue of some provision of the Medical Practice Act or other statutes in *pari materia*, such as the Chiropractic or Osteopathic Acts of 1922."

"It Is a Serious Condition," concludes the Boston Medical and Surgical Journal, editorially (August 27, 1925), "when the state and nation takes upon itself the long-established prerogatives of the individual unless the individual fails to meet the requirements of society. We can understand the necessity of state or county hospitals in communities too poor or otherwise unable to provide them, but we believe that the creation of hospitals should be determined by definite indications rather than general principles."

Special Agent Henderson Reports to the Board of Medical Examiners that in the case of the People v. Fong Wan, Chinese herbalist of Oakland, said individual was "found not guilty by a jury in Department No. 2 of the Police Court of the City of Oakland." This, in spite of the fact that the People produced six witnesses who testified positively as to the pulse diagnosis and treatment given by the defendant on or about the date mentioned in the complaint."

Henderson reports that when Fong Wan was tried in the Oakland Police Court on January 29, 1925, he took the stand, testifying that he was a merchant, engaged in business at 576 Tenth street, selling rice, tea and herbs, etc., and denied that he had felt the pulse of the four witnesses who had testified to that effect.

In commenting upon this report, Doctor Pinkham, Secretary of the Board of Medical Examiners, considers it "added evidence of the difficulties they have in endeavoring to convict Chinese herbalists of violation of the Medical Practice Act."

Keep it up. You can at least make fakirs more careful in the language they employ, and now and then one may be proved so obviously guilty that some of our police courts will scold him.

Sutter Hospital—We welcome to our ethical advertising space in this issue the Sutter Hospital of Sacramento. This hospital is one of the splendid new modern health agencies of California, operated and directed by members of the California Medical Association, and is entitled to the consideration of physicians in its own territory and to the consideration of physicians who are referring patients from distant points.

The advertising pages of CALIFORNIA AND WESTERN MEDICINE are becoming more and more occupied with the announcements of creditable medical agencies of one sort or another, and no other kind can buy space in any of its issues. Physicians and other readers of this magazine may rely with confidence upon the reliability of service and information they will receive by application to this or any other hospital whose announcements are carried within our covers.

"The Physician Has Something to Sell," says William C. Woodward (Federation Bulletin), "when he offers his services to the community. The medical practice law ordains that what he offers for sale shall not be below a given standard, under penalty of fine and imprisonment. If I employ a physician and he does not give service of that quality, he offends not only against my private rights, but also against my rights as a member of the community. For any offense against my private rights, I am entitled to redress by civil suit, and the courts are open to me. For any offense against my rights as a member of the community, I am entitled to demand of the duly constituted law enforcement agencies of the

state that punishment be meted out against the criminal."

"The vendor of food offers the community food; the physician offers service. The vendor of food must offer food of a given quality; the physician must offer service of a given quality. Either may be penalized in case of default. Both are required to deal fairly and honestly with those who seek service or goods. Look at our medical practice law from that standpoint and you get a true understanding of its place among the laws of the community."

A Visiting Dietetic Service—We do not need more doctors as much as we need better articulated and more completely rounded contacts between the doctor and his patients. The pharmacist serves both the doctor and his patient in one important phase of health; the nurse, the physiotherapist, and the laboratory worker are equally effective in other phases of successfully co-ordinated health efforts.

Now come Miss Evaline Kerr and Miss Beth Dysart, pioneering in the exceedingly important field of dietetics. The growing importance of intelligent food service in health betterment is widely recognized. Such service is now justly looked upon as being as important as any of the other special services in all worthwhile hospitals and other health-serving institutions. But it is only now that we have the initial effort to extend this skilled technical help to patients in their homes. Visiting dietitians, working with and under the instructions of the doctor, are every bit as important a feature of successful medicine today as are nursing, pharmacy, physiotherapy, or any other of our health agencies and services. Nor is this all. It is no more possible or desirable for a doctor to know or remember all the technical points in the selection, preparation and serving of the most important of all his remedies—food—than it is incumbent upon him to know the technical problems of nursing. There are too many people practicing medicine under the guise of dietetics, and too few dietitians who are assisting doctors.

We feel that Miss Kerr and Miss Dysart are pioneering in a highly commendable venture, and we wish them success in the interests of better medicine and better health, more economically served for everyone. Their card will be found in our advertising pages.

Scientific Ethical Physiotherapy is still making progress in California. We welcome to our paid space, beginning with this issue, the physiotherapy laboratory of Lois M. Kendall, B. A., and George S. FitzJohn. Scientific technical physiotherapy is practiced in this laboratory by people thoroughly qualified and experienced, only under prescription of doctors of medicine. Their laboratory is located in the new Medico-Dental building.

Lippman and Sugarman Laboratory—We are glad to welcome to our advertising pages the Lippman and Sugarman Laboratory, as an ethical, essential agency in the progress of scientific medicine.

Doctor Lippman and Mr. Sugarman merit the approbation of physicians for their fine ethical stand in declining to carry their card in an official ethical medical journal until one of their members, Doctor Lippman, had secured his M. D. degree and license to practice medicine in California, even though they were not making diagnoses or otherwise practicing medicine. Thus, we see a splendid example of the influences of the moral code that governs physicians as it applies to right-thinking men even before they are fully qualified to assume responsibilities in the practice of medicine.

Examination for Public Health Nursing Certificate—The next examination for this highly prized certificate will be held at San Francisco and Los Angeles on Saturday, December 12, 1925.

Applications to take this examination must be filed with the State Board of Health not later than November 20. Blanks may be obtained from the offices of the board at Sacramento, San Francisco, or Los Angeles.

Under the legal requirements established by the Board of Health, eligible applicants for the examination shall be:

1. Registered nurse under the laws of California.
2. Shall have completed a public health nursing course

of from four to eight months in a school approved by the California State Board of Health, or

3. Shall have completed at least a semester (four months) of post-graduate work in social service, including theory and practical work, or

4. Shall present evidence of having engaged in general public health nursing for at least two years in connection with a public health organization approved by the California State Board of Health. (See paragraph 7.)

5. All applications for examination as public health nurse shall be filed in the office of the California State Board of Health, State building, San Francisco, and shall be passed on by a committee of the board.

6. Upon examination, credit of 5 per cent will be given to applicants who have completed a four months' course in public health nursing, and 10 per cent to applicants who have completed an eight-months' course in public health nursing.

7. On and after June, 1926, presentation of evidence of having attended a summer course of at least six weeks at the University of California at Berkeley or Los Angeles, or a course of equal standard at any other university, shall be required in addition to two years' practical experience.

8. All applications shall have attached to them an affidavit sworn to before a notary public, as to qualifications outlined in paragraphs 2, 3, 4, and 7.

William McFee, writing in *The Nation's Business*, says: "I can produce a business man who knows exactly what he is talking about, who will show that, of every dollar given to a certain organization, the ultimate beneficiary receives something less than 15 cents, the other 85 going in 'overhead,' stationery, salary of staff, purchase of mailing lists, and an elaborate propaganda that swamps the ordinary citizen until he becomes callous and drops the whole mess in the waste-paper basket."

In commenting upon the statement editorially, *The Dearborn Independent* believes that:

"There needs to come a wholesale exposure of all sorts of professionalism in every kind of so-called 'welfare' work—industrial, educational, and religious."

The Card of E. S. Pomeroy, M. D., Urologist, Salt Lake City, Utah, will be found in this and subsequent issues of CALIFORNIA AND WESTERN MEDICINE. Doctor Pomeroy is the first member outside of California to place his name in a dignified manner before his colleagues who receive CALIFORNIA AND WESTERN MEDICINE monthly.

More members of other state medical associations seem to appreciate the value of these cards in their official publications, as judged by the space they occupy, than do many of the members of California, Utah, and Nevada. Some of the other official medical journals contain as many as twelve or fourteen pages of these cards.

"There Never was a Time Until Now," concludes the *Journal Indiana Medical Association*, "when the medical profession, as a profession, stood in greater danger of losing its economic and social standing, and the time is ripe for active and drastic action that will tend toward self-preservation. . . . We may be accused of being alarmists, but we venture to say that within the next five or ten years medical men, individually and collectively, will be fighting for their very existence unless they adopt some means for self-preservation."

"Dr. Leonard L. Landis of New York, who styles himself the 'chairman of the American Association of Independent Physicians,' is trying to point the way to success in the practice of medicine through the medium of a book he is trying to sell. We hope," says the *Journal Indiana Medical Association*, "that no members of our association will bite at the bait thrown out. According to the *Journal of the American Medical Association* of June 13, 1925, Landis is the individual who did conduct a medical institute in New York City under the title of 'House of Health,' and New York papers at different times have recorded the arrest of Landis, both by federal and local authorities, in connection with unsavory medical activities. A renegade physician like Landis deserves

no recognition of any kind whatsoever from reputable medical men."

These quotations should prove sufficiently enlightening to the several Western physicians who have written CALIFORNIA AND WESTERN MEDICINE inquiring about Landis.

We Get an Interesting Insight into human nature as it is and always has been, in the remarkable "news value" attached to a charitable contribution "*to be used without red tape.*"

A Mr. Conners recently gave a million dollars to be used for any worthy purpose *wherever and whenever* it was needed and *without* red tape. Old-fashioned charity, as the Master defined and sanctified it, is not so common nowadays. Red tape—government or organization—is the prominent feature. Led by visionaries, we are trying to convert charity into "Big Business. We are debasing the sanctified purposes and methods of charity, and we are certain to fail. Already the handwriting on the wall is clear in some centers, and it is safe to prophesy that the Big Business, wholesale, impersonal method of giving will pass as people become disillusioned.

Material assistance is the least helpful phase of true charity, and when handled as Big Business is handling it "charity" tends to debase character and encourage thriftlessness.

Every Doctor Interested in Medical Economics should read (Illinois Medical Journal, September) the address given by President J. H. Mitchell before the annual meeting of the Chicago Dermatological Society. And don't overlook the discussion.

"Health Institutes of Dubious Reputation are having tough-going since the A. M. A. took a crack at them at the Atlantic City session. The public might as well know that practicing medicine by proxy through intermediaries, by mail, or under the auspices of lay organizations, is not very trustworthy and usually is dangerous. —Journal Indiana Medical Association.

"Water, Water Everywhere—"—There appears in this issue of CALIFORNIA AND WESTERN MEDICINE a new advertisement of drinking waters. This advertisement will continue to run for a number of months—we hope indefinitely—and the advertisers have chosen to utilize extracts from the highest scientific authorities, including the A. M. A., as the basis for their claims of the advantages of drinking "pure water."

No individual physician, no organization, no public body has greater responsibilities nor greater opportunities for error than is inherent in the promotion of drinking water, one of the fundamental essentials of human life. CALIFORNIA AND WESTERN MEDICINE could have the majority of its available advertising pages filled with highly paid propaganda for this and that water, alleged to accomplish this and that medical and health purpose. Ninety-five per cent of the claims of these waters, as is well known to physicians everywhere, are based upon ignorance or cupidity. Certain "mineral waters" contain well-known chemicals that have certain uses in the treatment of certain conditions. There is no more reason why these remedies should be prescribed indiscriminately for everybody than there is why the salts and other substances they contain should be universally prescribed from drugstore bottles because they happen to be indicated, in the opinion of competent physicians, for the ailments of certain individual patients.

In a word, wholesale prescribing of mineral waters—if in fact they *are* mineral waters—through advertisements in the secular press, merits exactly the same condemnation that is handed out to the patent medicine interests who propagandize very often the very same salts put up in bottles and sold over the drug counter.

CALIFORNIA AND WESTERN MEDICINE refuses to accept advertisements from "mineral water" companies making inordinate therapeutic claims in their copy to be published with us or in any other copy distributed by them in any manner whatsoever. Under that rigid rule we have, out of the hosts of applications, accepted within the last four

years only the advertisements of Puritas Water Service, Calso Water Company, Shasta Water Company, and Bartlett Springs Company.

This matter is being treated editorially at this time purposely with the hope that we may secure comments and reactions favorable or unfavorable to our policy from physicians or other persons who are as keenly interested as we are in the promotion of all that is good and in the condemnation of all that is bad, whether it be water or other substances—this purely in the interests of the personal and public health welfare of our citizens.

Treatment of Pertussis by Roentgen Ray—This paper, by Lawrence W. Smith, Henry I. Bowditch, Ralph D. Leonard, Paul W. Emerson, Edwin T. Wyman, Elmer W. Barron, Hyman Green, Elliott Hubbard and Max Tennis, Boston (Journal A. M. A.), represents an attempt to summarize the outstanding clinical and laboratory findings in 850 cases of pertussis treated by the roentgen ray. Of the 850 cases, 750, or 88.2 per cent., occurred under 7 years of age, and 260, or 30.5 per cent. of this group, were in infants under 2 years of age. Seventy-two cases occurred in infants under 6 months of age, with ten definite cases in infants under 2 months of age. This fact seems of considerable significance from the point of view of developing preventive measures, as the greatest mortality is well recognized to be in the younger age group. It is also interesting to note that while whooping cough ordinarily confers a permanent immunity like scarlet fever, typhoid and other infectious diseases, a second infection may occur, and three such cases were found among adults in this series, in which there was a very definite previous history of whooping cough in childhood, with the second infection usually contracted from a child in the family. The most important bit of knowledge derived from this study is that the infectious period of whooping cough is in the catarrhal stage and that it diminishes very rapidly after the actual paroxysmal period begins. The treatment of these cases has fallen into two main groups. First, the series treated by roentgen ray alone, and second, a group given combined vaccine and roentgen-ray therapy. There is a small series of controls which have not received treatment. The effects of the roentgen-ray treatment have confirmed in general the earlier results. Roughly, 80 per cent. of the cases have shown a definite diminution in the number and severity of the paroxysms in a time interval ranging from a few hours to a week or ten days. In some of these cases the clinical benefit has been extraordinary. This is particularly true of the group of infants with convulsions, as noted previously. In general, it is safe to conclude that the younger patients in the early paroxysmal stage show the most striking benefit. The next group in which the results are most striking is that in which the paroxysms have persisted for a considerable period of time. In this respect the treatment is not specific. It is interesting, however, that in this series of cases the best results were obtained in the post-pertussis type of persistent bronchial irritation. This benefit is shared about equally by the various age groups, although it is perhaps true that the younger patients do a little better. It does not seem necessary at this time to go further into statistical detail. In the second group, who have received both roentgen ray and vaccine, the percentage of patients benefiting seems to be practically the same, but the degree of benefit seems to be more marked, and the duration of the paroxysmal stage seems to be reduced more by this combined method of treatment than by roentgen ray alone. In both groups the treatment results, by the end of the second week almost invariably, and in many instances by the end of the first week, in a definite reduction of the size of the hilum lymph nodes and of the peribronchial thickening. This seems to parallel quite closely the clinical course of the disease, and it has been interesting to see how closely the roentgenologic interpretation of the chest films coincides with the history and physical findings of these cases. Certainly more than 80 per cent. of the roentgen-ray readings check almost exactly the clinical condition of the cases. These observations suggest that, by early diagnosis, adequate quarantine for the actual infective period can be required, with a concomitant decrease in morbidity and mortality.

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
 W. T. McARTHUR, M. D.....President-Elect
 EMMA W. POPE, M. D., San Francisco.....
Secretary and Associate Editor for California

ONE HUNDRED AND FIFTY-SIXTH MEETING OF THE COUNCIL OF THE CALIFORNIA MEDICAL ASSOCIATION.

Held in Conference Room No. 3 at the Biltmore, Los Angeles, California, Saturday, September 26, 1925, at 10 a. m.

Present—Doctors Parkinson, Kiger, De Lappe, Beattie, Smith, McLeod, Peers, Kress, Shoemaker, Gibbons, Curtiss, Ewer, McArthur, Pope, and General Counsel Peart.

Absent—Doctors Kinney, Edwards, Coffey, Bine, and Catton.

Invited—Doctor MacGowan.

Minutes of the Council—On motion of Gibbons, seconded by De Lappe, it was

RESOLVED, That the minutes of the 152nd, 153rd, 154th, 155th, and 156th meetings of the Council, as mailed to each member thereof, be approved.

Minutes of the Eighty-third Meeting of the Executive Committee—The secretary read the minutes of the eighty-third meeting of the Executive Committee, held Thursday, June 18, 1925.

Action by the Council—On motion of De Lappe, seconded by Gibbons, it was

RESOLVED, That the minutes of the eighty-third meeting of the Executive Committee be approved as read.

Minutes of the Eighty-fourth Meeting of the Executive Committee—The secretary read the minutes of the eighty-fourth meeting of the Executive Committee, held Tuesday, June 30, 1925.

Action by the Council—On motion of McArthur, seconded by Ewer, it was

RESOLVED, That the minutes of the eighty-fourth meeting of the Executive Committee be approved as read.

Minutes of the Eighty-fifth Meeting of the Executive Committee—The secretary read the minutes of the eighty-fifth meeting of the Executive Committee, held Thursday, August 6, 1925.

Action by the Council—On motion of Ewer, seconded by Kiger, it was

RESOLVED, That the minutes of the eighty-fifth meeting of the Executive Committee be approved as revised.

Financial Statements—Financial statements for June, July, and August, 1925, were approved as submitted, as follows:

June, 1925

Total receipts for June.....	\$ 4,036.65
Total expenses for June.....	5,610.10

Loss for June.....	\$ 1,573.45
Net Gain for five months.....	24,079.34

Total net gain for 1925.....	\$22,505.79
------------------------------	-------------

Cash on hand—Bank, January 1, 1925	\$18,790.11
Cash on hand—Revolving Fund	200.00

Date of 1926 State Meeting—The secretary stated that the date of the 1926 meeting of the American Medical Association had been fixed as of April 19 to 23, to be held in Dallas, Texas. The Executive Committee recommended that the California Medical Association hold their meeting the week following, from April 26 to May 1, inclusive; the first two days to be called the pre-convention period, the last four the convention proper; and that speakers from the American Medical Association be invited to conduct pre-convention clinics on the mornings of April 26 and 27. The question of paying the expenses of the invited speakers was discussed.

Action by the Council—On motion of De Lappe, seconded by Dudley Smith, it was

RESOLVED, That the date of the 1926 meeting be fixed as of April 26 to May 1.

On motion of Kress, seconded by Smith, it was

RESOLVED, That the Program Committee be authorized to select the speakers for the pre-convention period, and that the expenses of such speakers be defrayed by the society, viz., hotel expenses and railroad fare, and expenses from Dallas to Oakland and return.

Amendments to the By-Laws—The secretary presented the proposed amendments to the By-Laws, Chapter III and Chapter VI. After discussion the Chair appointed the General Counsel and Doctor Kress a committee of two to consider the advisability of the changes and to report at a later meeting.

Amendments to Constitution of California Association of Medical Social Workers—The secretary reported that if the proposed change raised the standards of social workers Doctor Musgrave favored it, and stated that Mr. Sullivan requested further time for consideration and investigation. It was the sense of the Council that action be deferred pending Celestine J. Sullivan's report.

Signature on Vouchers—The secretary spoke of the advisability of authorizing a third person to sign vouchers for the association, and recommended that in the absence or illness of either member of the Auditing Committee, the president or the president-elect be authorized to sign vouchers.

Action by the Council—On motion of Kiger, seconded by Gibbons, it was

RESOLVED, That the president or president-elect be authorized to sign vouchers in the absence or illness of either member of the Auditing Committee.

Health Insurance for California Medical Association Employees—The question of health insurance for California Medical Association employees was discussed. The secretary submitted reports from various companies. After discussion it was decided that the Order of Railway Employees offered the most favorable opportunities.

Action by the Council—On motion of Peers, seconded by Shoemaker, it was

RESOLVED, That the office staff of the California Medical Association be insured for health and accident in the Order of Railway Employees, and that these policies be written to cover all assistants to the secretary and editor, and that the entire premium be paid by the California Medical Association.

Redistribution of Councilor Districts—The secretary reported that councilor action controlled redistribution of councilor districts and requested action on the change of Kern County from the second to the fourth district, and of Orange County from the first to the second district.

Action by the Council—On motion of McArthur, seconded by Kiger, it was

RESOLVED, That the Council approve the change of Kern County from the second to the fourth district, and Orange County from the first to the second district.

State Program—The secretary submitted the plan approved by the Executive Committee for state program and suggested that the Oakland Committee on Arrangements have charge of the pre-convention clinics, and reported that the Committee on Arrangements requested permission to have smokers on Wednesday and Friday evenings.

Action by the Council—On motion of Kiger, seconded by Kress, it was

RESOLVED, That the program as submitted be adopted; that the Program Committee have charge of the convention clinics, but may co-operate with the Arrangements Committee, and that smokers be deferred until the close of the House of Delegates meetings.

Physicians Income Tax Deductions—Granville MacGowan presented correspondence had with W. C. Woodward, Secretary Bureau of Legal Medicine and Legislation of the American Medical Association, and Senator Shortridge, and submitted the following resolution:

WHEREAS, The California Medical Association believes that the amendment about to be made to the Income Tax law should, in fairness and justice, include the specific allowance as deductions from taxable income, of the expenses of professional men while engaged in post-graduate work and study; now, therefore, be it

RESOLVED, That Honorable Hiram W. Johnson and Honorable S. M. Shortridge, Senators from California, and the Representatives from California, be respectfully requested to use their best efforts to embody such amendment in the revision of said law in the coming session of Congress; and be it further

RESOLVED, That a copy of this resolution, together with copy of the proposed amendment to the Income Tax law be furnished to each of said Senators and the Representatives from California.

It was the sense of the Council that the report of the chairman be accepted with approbation and warm commendation.

Adjournment—There being no further business, the Council adjourned to meet in the same room at 2 p. m.

Held in Conference Room No. 3 of the Biltmore, Los Angeles, California, Saturday, September 26, 1925, at 2 p. m.

Present—Doctors Parkinson, Kiger, De Lappe, Beattie, Smith, McLeod, Peers, Kress, Shoemaker, Gibbons, Curtiss, Ewer, McArthur, Pope, and General Counsel Peart.

Absent—Doctors Kinney, Edwards, Coffey, Bine, Catton.

Hospital Bond—Report by secretary. Letter from Rene Bine submitted. It was the sense of the Council that the secretary be instructed to write the insurance company and ask their representative to get in touch with the General Counsel, as complaints from several hospitals have been received.

Membership Directory—The secretary advised that if telephone numbers were included the cost of the membership directory would be approximately \$2000. Advisability of including telephone numbers was discussed.

Action by the Council—On motion of Kress, seconded by De Lappe, it was

RESOLVED, That the association hold to the form instituted last year: that the price of the directory be fixed at \$1; and that upon recommendation of the secretary, telephone numbers be omitted.

History of the California Medical Association—Letter from Emmet Rixford, chairman of the committee, was submitted. The secretary advised that Doctor Rixford was unable to submit a progress report, having just returned from Europe. Doctor Rixford requested information as to the field to be covered, and ruling as to where the data collected was to be stored.

Action by the Council—On motion of Kress, seconded by Smith, it was

RESOLVED, That the chairman of the Council should be empowered to enlarge the Committee on Historical Research to such number as will permit of securing suitable material locally; and that the material accumulated be placed in the Lane Medical Library, San Francisco.

Committee on Prenatal Care—The secretary advised

that the report of Reginald Knight Smith, Chairman of the Committee on Prenatal Care, had been received. Discussion was had as to the cost of publication and method of distribution.

Action by the Council—On motion of Kress, seconded by Shoemaker, it was

RESOLVED, That the final report of Reginald Knight Smith be accepted with thanks and referred to the Executive Committee with power to have same printed and distributed.

Clinical Prizes—The secretary informed the Council that Doctor Hewlett had tendered his resignation as chairman of the committee, on account of illness.

Action by the Council—On motion of McArthur, seconded by Shoemaker, it was

RESOLVED, That the resignation of Doctor Hewlett be accepted with regret; and that the question of clinical prizes and rules governing same be referred to the Executive Committee.

Industrial Medicine Practice—The resignation of Doctor Sol Hyman, chairman of the committee, was submitted to the Council.

Action by the Council—On motion of Kress, seconded by Shoemaker, it was

RESOLVED, That the resignation of Sol Hyman, as chairman of the committee, be accepted with regret, and that the best thanks of the Council be given for the generous service rendered.

Application for Associate Membership—Morton R. Gibbons reported that Doctor Leach had joined the Alabama Medical Society, and therefore wished to withdraw his application for membership in the California Medical Association.

Yosemite Hospital—The secretary reported on letters received from various Congressmen, advising that \$35,000 for the building of a hospital at Yosemite has been included in the yearly budget.

Medical Officers' Reserve Corps—Letter from J. Wilson Shields, chairman of the committee, was read by the chairman.

Auditors for 1925—The secretary submitted a report on auditors for 1925. It was the sense of the Council that the secretary be authorized to employ Hugh Ross to audit the books for the association for the current year.

Sciences Allied to Medicine—Letter from Doctor Olin West, Secretary of the American Medical Association, was read by the chairman. No action taken.

Advertising by Journal—The secretary brought up the request of the editor for space in "Western Advertising."

Action by the Council—On motion of De Lappe, seconded by McArthur, it was

RESOLVED, That the editor of the Journal be authorized to advertise CALIFORNIA AND WESTERN MEDICINE in the January, 1926, issue of "Western Advertising."

Request From American Medical Association Legal Department for Opinion of Council on Traffic Laws for Physicians—Letter from William C. Woodward, Secretary Bureau of Legal Medicine and Legislation, American Medical Association, was read by secretary, and the question of various insignias used by physicians discussed.

Action by the Council—On motion of Kress, seconded by Smith, it was

RESOLVED, That the General Counsel be requested to investigate this question and submit to the Council at a subsequent meeting such suggestions as he may deem proper.

Communication from W. C. Woodward to be acknowledged and placed on file.

Model Constitution and By-Laws for State Societies—The secretary presented copy of Model Constitution and By-Laws, furnished the society by Olin West, Secretary of the American Medical Association.

Action by the Council—On motion of Kress, seconded by Kiger, it was

RESOLVED, That the secretary be requested to write to the American Medical Association for sufficient copies, to permit mailing one to each member of the Council; and that, meanwhile, the matter be referred to the General Counsel for investigation.

Appointment of Member on the Scientific Program to Fill the Unexpired Term of Roland Skeel—The

Council was advised of the death of Roland E. Skeel, member of the Committee on Scientific Program, and it was suggested that the secretary of the Section of General Medicine or Surgery succeed him.

Action by the Council—On motion of Shoemaker, seconded by Gibbons, it was

RESOLVED, That J. Marion Read, Secretary of the General Medicine Section, be appointed to fill the unexpired term of Roland E. Skeel on the Scientific Program Committee.

Held in Conference Room No. 3 at the Biltmore, Los Angeles, California, Saturday, September 26, 1925, at 8 p. m.

Present—Doctors Parkinson, Kiger, De Lappe, Smith, Kress, Shoemaker, Gibbons, Ewer, McArthur, Pope, and General Counsel Peart, and members engaged in Industrial Medicine at Los Angeles and vicinity, by invitation. (About twenty-five in all.)

Absent—Doctors Kinney, Edwards, Beattie, Coffey, McLeod, Peers, Bine, Curtiss, and Catton.

Industrial Medicine Practice—The question of Industrial Medicine practice was brought up, and the General Counsel submitted rules governing same. After full discussion, it was the sense of the Council that the General Counsel should prepare revised rules, as discussed in detail at the meeting, copies of which would be sent to the secretaries of the San Francisco and Los Angeles societies, and each member of the committee of fifteen for suggestions, after which they would again be referred back to the Council.

Committee on Publicity—Doctor Kress submitted the following further report for the Committee on Publicity:

"On the subject of securing wider publicity among the laity on matters having to do with the conservation of the public health, it is the sense of this Board of Councilors of the California Medical Association that the public health activities of the League for the Conservation of Public Health have the endorsement of this Council; and that county medical units of this California Medical Association be urged to secure the fullest possible co-operation of their members in the work of the League, and, further, that the Council urges all other public health agencies desiring to carry on work in California having similar objects to those of the League for the Conservation of Public Health to co-operate in fullest harmony and measure with the said League."

It was the sense of the Council that copy of the resolutions of the Council be sent to the Gorgas Memorial, and copy also be sent to Doctor James F. Percy for his information.

Amendments to the By-Laws—The General Counsel submitted the following amendment to Chapter III of the by-laws of the California State Medical Association.

CHAPTER III

No delegate or alternate whose name has not been certified in writing as such by his county unit, through its president or secretary, and filed in the office of the secretary at least seven days prior to the annual meeting shall be entitled to a seat in the House of Delegates; and no delegate absent, without prior notification to his county secretary or secretary of this association, shall be eligible for representation the following year; and it shall be the duty of the secretary to mail a list of all absent delegates to the proper county units.

Action by the Council—On motion of Kress, seconded by Smith, it was

RESOLVED, That the amendments to Chapter III of the by-laws of the California Medical Association be approved as read, and recommended to the House of Delegates for adoption at the next meeting thereof.

Adjournment—There being no further business, the meeting adjourned.

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The meeting of the association was held Monday evening, September 21, President Mehrmann in the chair.

Edgar Lorrington Gilcreest, M. D., in his paper, "Luncheon Glimpses of Sir William Osler During the

World War," gave personal reminiscences of this great physician as he saw him during the World War, where he was consultant to one of the hospitals in Southern England in 1915, where Dr. Gilcreest was serving at that time with the American Red Cross. He did not attempt to give a biographical sketch of Osler, but concerned himself chiefly with the personal and human side. He pointed out Osler's bright philosophy, and told many stories which revealed his inimitable charm and magnetism. His influence, he said, affected the destinies of young men who studied under him more than any teacher of his generation. How Osler revolutionized the teaching of medicine on this continent makes one of the most brilliant chapters in medical history, and is in part responsible for the high place which America enjoys today in the scientific world. He related that it was Osler's book, "The Principles and Practice of Medicine," which attracted the attention of Mr. Rockefeller, whose interest in medical research culminated in the establishment of the Rockefeller Foundation, and whose total contributions reached, the week that Osler died, the colossal sum of \$300,000,000. Dr. Gilcreest continued by saying if these millions had not been turned into this channel for the alleviation of human suffering all over the world, inestimable, indeed, would have been the loss to the world. His high place in medical history as a physician is assured, but he should also have, and with an increasing knowledge of his work will have, a high place in the minds of all as a philanthropist.

"Some Causes and the Care of Stammering—A War-time Development" was the subject of Mr. Robert Lloyd's address. He based his conclusions on a lifetime study and practice of the voice, as a public singer, teacher and lecturer. He affirmed that there are fixed laws which govern all uses of the voice, and demonstrated these laws in the course of his address, and stated that once understood and learned, the use of these laws would relieve any case of stammering. He also told of his army experiences as instructor in six different camps, during which time the impressive total of 350,000 men went through his classes.

On September 27 the American Women's Overseas League of San Francisco and the Eastbay regions held exercises at the U. S. Veterans' Hospital at Livermore, dedicating the women's ward. With the opening of this hospital last April, the Veterans' Bureau established a women's unit of twenty-four beds for the treatment of disabled ex-service women. The American Women's Overseas League assumed the responsibility of beautifying this ward. They furnished its large recreation room in a most attractive and artistic manner. Upon completion of this work, dedication exercises were held, to which the friends of the American Women's Overseas League and the public-at-large were invited to see what had been accomplished and to dedicate it to the service of the disabled ex-service women. Miss Marian Crocker, president of the American Women's Overseas League of California, introduced Mrs. E. K. Sturgis, chairman of the Hospital Committee, who made a beautiful and appropriate address before a large audience. One of the ex-service women patients replied by expressing their appreciation for the splendid things the American Women's Overseas League had done for their comfort and happiness. Other speakers on the program were Mr. John Garthwaite, chairman of the day; Congressman Albert E. Carter, Mr. Joseph R. Knowland, and Colonel P. S. Rawls, medical officer in charge of the Veterans' Hospital at Livermore.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the Contra Costa County Medical Society was held Saturday evening, September 26, at the Abbott Emergency Hospital, Richmond.

Walter C. Alvarez, M. D., of San Francisco lectured on the diagnosis in relation to the digestive tract. It was a most valuable lecture; it covered the ground that any general practitioner or specialist, no matter what line he is in, will meet daily. The doctor is an interesting lecturer, and will be welcome in the future to our society.

The next meeting will be held at Walnut Creek, in October. The society have their minds set upon a moving

picture machine, which will be used during the coming winter.

S. N. Weils of Selby was elected a member, and we are sure he will be a valuable acquisition. The following were present:

G. M. Bumgarner, Denninger-Keser, H. L. Carpenter, Hall Vestal, L. St. John Hely, E. R. Guinan, Mrs. Gardell, R. N., Mrs. Purviance, R. N., Richmond; Agnes Driscoll, R. N.; Clara Thompson; C. E. Camp, San Pablo; S. N. Weil, Selby; J. W. Bumgarner, M. D.

SACRAMENTO COUNTY

Sacramento County for Medical Improvement (reported by Bert L. Thomas, secretary)—The largest attended regular meeting of the Sacramento Society for Medical Improvement was held at the Sacramento Hotel on Tuesday, September 15, 1925. Fifty-eight doctors were in attendance. These included Doctors Farmer, Farrell, Scatena, Zimmerman, Thomas, Nahl, Windmuller, Turner, H. Hall, W. E. Briggs, Fay, Cress, Yates, McMullin, W. R. Briggs, Schoff, Loizeaux, Pitts, Foster, Thom, Wells, G. Hall, Azevedo, Schluter, Babcock, Beach, Wahrer, Baird, Scribner, Dillon, C. B. Jones, Lindsay, Snyder, Wilder, Christman, Howard, Hagerty, Lipp, Grazer, Reardan, Klick, Brendell, Krull, Brown, Burden, Burke, Schell, Captain Mix, Drew, and Eber. The minutes of the June meeting were read and approved. No case reports.

The paper of the evening was ably presented by Harold Zimmerman; its title was "The Present Status of X-ray Therapy." Zimmerman reviewed the early history of this particular treatment. He compared the various rays with other forms of energy; pointed out the difference between hard and soft rays, the use of screening, the methods of application, the usual dosages, and described various methods of determining exact dosages in different parts of the body. He carefully grouped type doses into three classes—those that stimulate, those that inhibit, and those that destroy. Under this classification a vast army of pathological lesions were briefly reviewed. In the discussion of the paper, Schoff pointed out that few skin men use screening. They take advantage of the soft ray, as well as the hard ray. He reviewed the present status of the use of the ray in psoriasis, hyperidrosis, ringworm, epilation, and on various types of warts. Thom described the apparatus used, at the present time, at the Sutter Hospital. He mentioned, in addition, that x-ray dosage was now as clearly defined in therapy as any of the more exact drugs that are included in the last edition of the Pharmacopeia. Wahrer inquired about the authenticity of one of the statements made by Zimmerman "that on several occasions it had been noted, after x-ray therapy had been applied to a cancerous tumor, distant tumors had retrogressed without any direct application of the ray." He attributed this to the probable formation of antibodies to attack the cancer at a distance. In closing, Zimmerman regretted the fact that W. A. Briggs, the dean of x-ray therapists in these parts, could not add to the evening's paper. In answer to Wahrer, he stated that the observations quoted above did occasionally occur; the surmise of antibodies is merely theoretical.

Applications of Charles I. Titus, Clyde G. Reynolds, Edward P. Moser, and Hans Frank Schluter were read for the first time.

Communications were introduced from Mrs. Brittain regarding the Exchange; Mrs. Mortell, regarding her collecting system, and from Colonel Edward L. Munson, regarding the organization of a hospital train and medical laboratory, from within the membership of the society.

Brendell moved, and Reardon seconded, that the society go on record for sponsoring the Medico Military Units allocated to this community, and that a questionnaire be prepared by the secretary to inquire about the possibility of supplying the medical personnel required for this service. Motion carried.

The meeting adjourned to the banquet hall, where not the least interesting portion of the evening was spent in listening to W. E. Briggs relate interesting excerpts from his trip around the world. Farmer and McMullin also added complimentary remarks to close the evening.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—A meeting was held October 6 at Loma Linda. There were fifty present. The meeting was called to order by the president at 7:30. The minutes of the previous meeting were read and approved. Report of the secretary-treasurer was read and accepted. Dues for the ensuing year were fixed at \$15. The following officers were elected: President, A. N. Donaldson of Loma Linda; First Vice-President, Walter Pritchard of Colton; Second Vice-President, K. L. Dole of Redlands; Secretary-Treasurer, E. J. Eytinge of Redlands.

Delegate for the state convention was elected: A. N. Donaldson.

Alternate for the state convention was elected: E. L. Tisinger.

After a banquet furnished by Loma Linda, the program was as follows:

Address by retiring president. Councilor's report by C. L. Curtiss. Address: "The Practice of Medicine Is a Religion," by Dr. Cornelius Van Zwalenburg.

The meeting adjourned at 10:30.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock)—The joint staff meeting of the County General and Mercy Hospitals, held in the auditorium of the former on the evening of September 22, drew a good attendance. Many interesting cases, medical and surgical, were exhibited and discussed by members of the house staff. A. E. Elliott gave an interesting report of the experimental work recently carried on by E. B. Mundkowski and himself in the x-ray laboratories of the County Hospital to determine the efficacy of certain salts, when taken by mouth, in outlining the normal gall-bladder. They are at present limiting their observations to the use of sodium tetraiodophenolphthalein, and while the results reported upon were of extreme interest, still they must be looked upon as but expressing a preliminary report. Dr. Graham's method of outlining the normal gall-bladder has opened up a new avenue of approach to the study of this very important organ.

The president of the society, George B. Worthington, presented some very entertaining reels of moving pictures which he had gathered on his recent journeys to the California State Medical Association meeting at Yosemite Valley and the meeting of the American Medical Association at Atlantic City and some of the Eastern clinical centers. This is expressive of a legitimate hobby for physicians which may be made productive of both education and pleasureable interest to themselves, as well as entertainment to their friends.

A goodly number of our members have expressed themselves as intending to visit the Southern California Medical Association meeting in Los Angeles the first week-end in November.

SAN FRANCISCO COUNTY

The Medical and Surgical Colloquia are again being held on Tuesdays and Fridays at the San Francisco Hospital. At the last Surgical Colloquium, Emmet Rixford occupied the time on "Cholecystectomy," and at the Medical Colloquium on Friday, Harold Hill presented a case of acute hemorrhagic nephritis.

St. Lukes Hospital Report—The August report of St. Luke's Hospital shows 4289 patient days service; 302 operations; 1872 laboratory and 717 radiology services. The hospital served 37,515 meals at a cost of \$7,209.40. One thousand two hundred and one patients had service in the out-patient department. This splendid hospital has instituted an innovation in the form of a printed monthly bulletin, or "house organ," for the information of officers and employes of the hospital.

St. Joseph's Hospital Staff Discusses Gastric Surgery and Diagnosis of Heart Disease—At a recent meeting of the staff of St. Joseph's Hospital, Ernst Gehrels discussed "Progress in Gastric Surgery."

"Splanchnic anesthesia after the method of Braun," said the speaker, "is of great advantage for gastric surgery and is employed as a routine, especially when oper-

ating upon cancer. The danger of fatal pneumonia is largely eliminated by local anesthesia.

For cancer of the stomach the Billroth II-Polya method is employed, using a long loop of jejunum and adding a jejunal anastomosis in order to prevent congestion in the afferent loop (leakage at the blind closure of the duodenum is mostly due to this). The late results after a radical operation for cancer are encouraging, more than 25 per cent of the patients being alive and free from symptoms after five years or more, in the experience of Payr.

"For ulcer of the stomach gastro-enterostomy alone is inadvisable, as there has been recurrence of symptoms in 50 per cent or more of the patients, and there remain late dangers after gastro-enterostomy—bleeding, perforation, cancerous degeneration and peptic jejunal ulcer. The methods used in forty-three resections for ulcer (with three deaths) are transverse resection (17 cases), polya (23), Schnieden's step-shaped resection (1), and Bilroth I-Goepel (2).

"The mortality of resection can be reduced to 5 per cent or less by good technique. Regarding late results, the radical operations do not entirely eliminate recurrence of ulcer, but from 90 to 95 per cent of the patients can be permanently relieved of all symptoms. The operation is indicated only for those patients who have proved to be incurable by medical treatment."

Harry Spiro spoke on "Modern Diagnosis of Heart Lesions," when he said:

"The spirometer is useful to determine vital capacity, and offers an index of improvement. Metabolism outfits determine thyroid disturbances chiefly, which may cause hypertension, myocarditis, endocarditis, and irregularities. The electrocardiograph is costly, but indispensable in the diagnosis of 10 per cent of patients with heart lesion. Aortic lesions, auricular fibrillation and flutter, and the proper treatment with digitalis and quinidine are best controlled by it. Heart-block cannot often be diagnosed without it. Radiology, if intelligently used, is important. Apex murmurs can be differentiated by placing the patient in certain angles, and angina pectoris of the aortic type, amenable to treatment, can be diagnosed from that of myocardial origin."

The program for the next one of these interesting and profitable staff meetings, to be held November 18, includes "Talma Operation for Cirrhosis," by P. Collischonn. "Diagnosis of Unruptured Ectopic Pregnancy," by David Stafford. "Double Unilateral Dermoid," by John Newton. "Notes From Eastern Medical Centers," by T. I. James. "Interesting Pathological Specimens," by W. T. Cummins. "Unusual X-ray Demonstrations," by L. B. Crow.

Sister M. Sylvia, Superior of St. Joseph's Hospital, is to be complimented upon the splendid progressive spirit she is developing in the large staff of her hospital.

✽

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (Philip C. Means, secretary pro tem)—The first meeting following the summer vacation was held September 14 in the staff room of the Cottage Hospital, Vice-President Henderson presiding.

Minutes read and approved. The application of William McKee Moffat was approved and he was elected to membership. Correspondence was read from the Association for Medical Progress, the state secretary, and Manager Curtis of the hospital. Action was deferred to a later meeting.

The first paper of the program was "Some Phases of the Treatment of Pulmonary Tuberculosis," by Edward W. Hayes, M.D., of Monrovia. It was of unusual interest and was the cause of much discussion, especially the phases of fresh-air baths, heliotherapy, diet, and the changes in our views of these factors.

Marian Williams, M.D., presented the late views and advances in the knowledge of anterior poliomyelitis, and the results of the Vermont survey and investigations, with the views of Lovett on treatment in the various stages. A very interesting and carefully prepared paper at an opportune time.

A regular meeting, according to Alex C. Soper Jr., secretary, was held at the Cottage Hospital Monday,

October 12, the second after the summer vacation. A study of fifty-six babies of the city, as presented by Horace Gray, M.D., under the title of "Observations on the American Legion Baby Show," proved an interesting analysis of a "cross-section" of infancy in the community.

The second paper of the evening, a surgical treatise on cancer of the colon, was not read, due to the temporary illness of its author. Correspondence and routine business occupied the time for a brief meeting.

✽

SONOMA COUNTY

Sonoma County Medical Society (reported by Guy A. Hunt, secretary)—The Sonoma County Medical Society met in Santa Rosa October 9. Doctor J. W. Seawell of Healdsburg gave a paper on "Urological Diagnosis by the General Practitioner." He also discussed a case of fracture of the sixth and seventh cervical vertebra, and one of collapse of the lung and showed x-ray films of each.

REPORT OF DELEGATES FROM THE C. M. A. TO THE A. M. A.

On account of the late date on which these reports were received by the editor, only abstracts are published:

Victor G. Vecki—Our State Society was entitled to five delegates, but was represented by only four: Albert Soiland, Los Angeles; Robert V. Day, Los Angeles; Lemuel P. Adams, Oakland; and Victor G. Vecki of San Francisco.

Soiland served on the Reference Committee of sections and section work. He displayed great ability and submitted the report of that committee in an excellent manner.

I submitted to the House of Delegates the following resolution:

BE IT RESOLVED, That, in order to protect the best interests of the public, and promote the welfare of the general physician, that

1. Each and every properly elected delegate to the A. M. A. be appointed a committee of one, whose duty it will be to visit, at least once a year, each county unit in his district.

2. That the A. M. A., as a body, will use all its resources in assisting the committees to convey information to the county sections, which will keep them informed of matters which are inimical to the best interests of scientific medicine.

3. That each committee must report, by a signed statement, the result of this visit yearly.

In his enthusiastically received address, President-elect Haggard emphasized most energetically that effective organization is absolutely necessary, and pointed out that the profession has no right to blame Congress or any state legislature unless it has brought the situation to their attention in a timely, intelligent, and effective way. To do this requires effective organization.

When the Board of Trustees reported on my resolution the day after, they said: "On the resolution of Victor G. Vecki, that 'each member of the House of Delegates visit each county in his jurisdiction, and that the board support this to the full extent of its resources,' the board recognizes that the principle underlying the resolution is sound. The board is now doing its utmost, and will continue to do all that it can to extend the visiting of official representatives to constituent parts of the association. In furthering this idea, the board will also make available to each delegate a digest of the proceedings of the annual sessions.

One of the most interesting features of the whole session was a visit from Honorable Hubert Work, the Secretary of the Interior, who was a member of the House of Delegates for eighteen years, its speaker for four years, and finally president of the American Medical Association. He did not forget his former associates, and delivered an address that warmed the heart of everyone present.

Albert Soiland—It has been my pleasure to serve the California Medical Association for five consecutive years as delegate. The 1925 session at Atlantic City was well attended, and the California delegation, consisting of

Vecki, Day, Adams and Soiland, were in evidence throughout the meeting.

Of the California delegates, Vecki easily shines as a leading light. His pointed remarks, tempered with wit and good humor, are always well received by the House.

The resolution on medical ethics, authorized by the California Medical Association, which I introduced before the House, was referred to the Judicial Council. The Council reported back as follows:

"With respect to the resolution offered by Albert Soiland of California, the Judicial Council is of the opinion that the constitution and by-laws of state and county societies provide for penalties to be imposed for violations of the principles of medical ethics, and that this is a matter for determination by those bodies."

This report, upon motion and seconded, was unanimously adopted.

For several years I have served on the Reference Committee on Sections and Section work, and this year during the temporary absence of the chairman, Dr. Abt, the speaker appointed me chairman pro tem., and in this capacity I had the pleasure to report to the House of Delegates that the committee had acted favorably upon a former resolution creating a section on radiology. This was of signal interest to me because I had personally been active in the work which made this section possible. It may be apropos to state that the meeting place assigned for the new section was filled to standing room only for each session—surely a sign that the section was in demand.

The business of the House of Delegates was executed with less friction and with more good feeling than at any former meeting which I have attended.

Lemuel P. Adams—I have only a brief report to submit.

I attended all of the sessions and was an interested spectator, but did not take any active part.

The routine business proceeded in a machine-like manner, and was satisfactory to all. I especially commend the stand taken on the Life Extension problem. Dr. Vecki, I am sure, will incorporate in his report all that would be of interest to our State Society.

H. Lissner—Much to my regret I was unable to go on to the American Medical Association convention last May, and therefore have no report to make. I am under the impression that my alternate, Doctor Stevens, was likewise unable to attend.

Robert V. Day—I haven't any report to make, and consequently it will not be necessary for you to arrange any time for me to speak.

CHANGES IN MEMBERSHIP

New Members—Bard S. Berry, Arthur E. Kaelbar, Robertson Ward, San Francisco; Clyde W. Bice, Frank R. Johnston, Oakland; Burfee Cooper, Hoopa, Humboldt County; Frank K. Haight, Scotia, Humboldt County; Claude E. Norris, Samoa, Humboldt County; George H. Rue, Calistoga; Lewis H. Sanborn, Represa, Sacramento County; John Milton Scanlan, Imola; James W. Sherrill, La Jolla; George S. Weger, San Diego.

Deaths—**Barton, Herbert P.** Died at Los Angeles, October 15, 1925, age 59. Graduate of Jefferson Medical College, Philadelphia, 1890. Licensed in California in 1898. Doctor Barton was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Dresser, Ralph O. Died at San Francisco, September 28, 1925, age 49. Graduate of the University of California Medical School, 1901. Licensed in California the same year. Doctor Dresser was a member of the San Luis Obispo County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Lux, Frederick William. Died at San Francisco, September 20, 1925, age 64. Graduate of the Medical School of Harvard University, Boston, Mass., 1885. Licensed in California the same year. Doctor Lux was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Taylor, Albert Miles. Died at San Francisco, Septem-

ber 18, 1925, age 67. Graduate of the Missouri Medical College, St. Louis. Licensed in California in 1889. Doctor Taylor was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

RONALD E. SKEEL, M. D.

1869-1925

Doctor R. E. Skeel of Los Angeles died September 4, 1925, of thyroid toxemia following a serious influenza in January, 1925, and acute heart exhaustion while in the operating room in June, 1925.

Doctor Skeel will be best remembered in Los Angeles for the work he did in connection with the campaign for hospital betterment of the last few years. Several Los Angeles hospitals owe much of their improved facilities to his knowledge and his vigorous way of demanding and pushing through reforms in method and practice. He had done much along the same line in Cleveland before coming to Los Angeles.

His unselfish uplift interest was further shown by his continued effort and work in behalf of the Permanent Home for the Los Angeles County Medical Association. An article contributed by him in Bulletin No. 4, February 19, 1925, more accurately illustrates his point of view.

Doctor Skeel was born at Fulton, New York, on February 9, 1869. Graduated from medical college at Ann Arbor, Michigan, 1890. Was an intern at Cleveland in 1891 and 1892. Was in practice in Cleveland from 1892 until 1920. Married Alva P. Boepplee in 1893. Has one daughter, Mrs. H. V. Lee of San Diego, Calif. Was given honorary degree of M. A., by University of Michigan in 1915. Also M. S., by Ohio Wesleyan in the same year. Was made dean of Cleveland College of Physicians and Surgeons in 1902, and remained in this position until the merger of this school with Western Reserve University Medical School in 1911. This merger was in large part due to his efforts. He taught both obstetrics and gynecology during his college work. Was president of American Association Obstetricians and Gynecologists in 1921-1922. His work on gynecology and pelvic surgery was published by Blackston's Son & Co. in 1916; also a second edition. Fellow of American College of Surgeons. Member American Medical Association. In 1917 he went to Europe and did volunteer work with both the French and British armies. Transferred to the American Expeditionary Force in 1918, and saw front line and all other kinds of surgical duty until mustered out with rank of major in 1919.

Utah State Medical Association

T. C. GIBSON, M. D., Salt Lake City.....President
 W. R. CALDERWOOD, M. D.....President-Elect
 FRANK B. STEELE, M. D., Salt Lake.....Secretary

Editorials by J. U. GIESY, Associate Editor for Utah

APPRECIATION

The year would scarcely be properly closed were one not to pay some mark of appreciation to the work of those men who have carried it through to such a successful close. Past President Sol G. Kahn's incumbency of the office he has just quitted certainly left little to be desired in the office of president. Deeply interested in the welfare of the association, he was tireless in his efforts to advance the interests of the medical profession in the state. How much he achieved can be seen better now in retrospect than when it was in course of being brought about. Retiring Secretary Rich is a veteran of years in the duties of the office he has now quitted, and no one need ask how well Bill Rich has served. His record stands for itself. For the other officers one and all, we have only words of thanks and words of praise. They have set a record which future officers may well strive to emulate. And this is meant to include the members of various committees who have been consistently steadfast in their work.

MEDICAL OFFICERS' RESERVE

Four medical units of the Reserve have been assigned to Salt Lake. The personnel will be made up from the personnel of the Medical Society—in the main, at least. It has been suggested by the Surgeon-General's office that once a year those members in the Reserve appear at a society meeting in uniform—this night to be known as Military Night. The matter has been referred to the committee, but personally we are for it. The Reserve is the backbone of the possible medical service in time of national emergency. And certainly the profession has every reason to be proud of the record made by the medical officers who forsook their private interests and donned the uniform in the last emergency of that sort.

Service is the real ideal of the doctor, in the army or outside of it. There is a bit of sentiment in a night set apart for those who might in such fashion show just how ready they are to serve.

Utah Notes (reported by J. U. Giesy, associate editor)—Past President Sol G. Kahn will leave next month for New York. The doctor is combining business and pleasure. While in the East he will attend the wedding of a relative, and do post-graduate work.

The Clinical Association of the Holy Cross Hospital held its first meeting of the winter season the evening of September 21. Drs. E. F. Root and W. G. Schulte spoke entertainingly on their experiences in the European clinics which they visited on their recent trip abroad.

J. U. Giesy and wife left October 4 for a trip to Omaha, Chicago, and New York. Dr. Giesy is a delegate to the American Legion National Convention at Omaha, whence he will continue East to attend the Convention of the American College of Radiology as a

speaker, go on to New York, and return the latter part of the month.

Several men of the local medical world are planning to attend the Interstate Post-graduate Assembly of America at St. Paul, October 12 to 16. The program, as furnished, would indicate that this meeting will be worth the while of anyone who is fortunate enough to hear it.

The present associate editor of CALIFORNIA AND WESTERN MEDICINE for Utah has just received orders from President Gibson of the Utah Association to stay on the job.

The secretary announces the appointment by President Gibson of the following Advisory Committee to the State Industrial Commission: Ralph C. Pendleton, Salt Lake; Jack Hosmer, Midvale; L. N. Ossman, Salt Lake.

Doctor C. H. Carroll, 1880-1925—Doctor C. H. Carroll, 44, died September 30 from an infection of the middle ear, following an illness of a week and a half. He was born November 6, 1880, at Orderville, Utah, and was a graduate of Rush Medical College of Chicago in 1920. He was formerly professor of biology at the Brigham Young University, Salt Lake, and at the time of his death was head of the health and zoology departments of that institution.

Dr. Carroll is survived by his widow, Elsie Carroll, dean of girls at the Provo high school; his parents, C. W. Carroll and Amelia Carroll; two brothers, Joe Carroll, professor at Stanford University in California, and William E. Carroll of Urbana, Ill., professor at the Agricultural College there, and a sister, Maurine Carroll of Provo.

The Salt Lake County Medical Society Meeting of September 14, 1925 (reported by M. M. Critchlow, secretary)—The meeting of the Salt Lake County Medical Society was held at the Commercial Club, Salt Lake City, Monday, September 14. President John Z. Brown, forty-one members and two visitors were present.

Applications for membership of Parley White, Silas Smith and Nephi Rees, were read and turned over to the Board of Censors.

The secretary read communications dated July 9 and July 10, 1925, from the office of the surgeon, headquarters Ninth Corps Area, San Francisco. These letters called attention to the fact that four medical units had been assigned to Salt Lake City personnel, of which it would be from members of our society for the most part. It was suggested that the County Medical Society sponsor these units as a form of special favor, and that the personnel should report in uniform at a regular meeting of the society once a year, to be known as Medical Military Night. T. A. Flood moved that the society endorse the records of the surgeon, but that it be referred to a special committee of three for action. Seconded and carried.

The first scientific paper was given by G. H. Pace, entitled "Concepts and Mental Mechanism of Insanity." The early concept of insanity was outlined and the theories of the cause of insanity discussed. The mechanism of insanity was illustrated by a case history, and the mechanism of several psychosis was discussed. This paper was discussed by F. J. Curtis, M. W. Baxter, W. R. Calderwood, and J. R. Llewellyn. In the discussion the necessity for a mental hygiene clinic in this city was stressed.

The second paper was read by L. C. Snow of Park City, entitled "Cerebrospinal Meningitis in Park City." His paper was based on a recent epidemic in spinal meningitis of six months, with six deaths. He reviewed the subject of spinal meningitis and discussed his experiences in the recent epidemic. This very instructive paper was discussed by E. R. Murphy, E. B. Isgreen, and T. A. Flood.

Meeting of September 28, 1925 (reported by Joseph E. Jack, treasurer and acting secretary)—A regular meeting of the Salt Lake County Society was held at the L. D. S. Hospital, Monday, September 28, President John Z. Brown in the chair. There were forty-three members and fourteen visitors present.

A communication from the Associated Retail Credit Men, regarding national "Pay your bills week," was received and read. Also a communication from Joel Rich-

ards, regarding a practice and hospital to be purchased in Pocatello, Idaho.

Application of Francis W. Brown for membership read, and referred to the Board of Censors.

Parley White, Silas Smith, and Nephi Rees were elected members of the society by unanimous vote of members present.

L. A. Stevenson had charge of the clinical meeting.

J. F. Sharp presented a case history and specimen of an interstitial ectopic gestation.

Roy Groesbeck presented a case of icterus, due to carcinoma of gall-bladder and liver.

Earl Skidmore presented a case of fecal fistula, following a ruptured appendix. Fistula had ruptured internally into peritoneal cavity. He also presented a case of abscess in stump of appendix, four years following ruptured appendix.

L. A. Thody showed some interesting x-ray plates.

D. G. Edmunds presented a case of peri-nephritic abscess.

Spencer Wright presented a case of possible hyper-nephroma.

Papers were discussed by A. Lipkis, L. L. Dains, Edmunds, Skidmore, Thody, J. Z. Brown, Young, and Goeltz.

Fred Stauffer reported on the Medical Arts building. Refreshments were served by hospital authorities.

ANNUAL REPORT

Transactions of the House of Delegates—Thirty-First Annual Meeting September 7 to 12, Inclusive, 1925

All meetings held at Stewart building, University of Utah, Salt Lake City, Utah.

SESSION NO. 1

The House of Delegates convened at 12 o'clock noon on Monday, September 7, 1925.

Meeting was called to order by the President, Sol G. Kahn of Salt Lake City; William L. Rich, secretary.

Moved, seconded, and unanimously carried that, inasmuch as the minutes of the 1924 meeting were printed in full in our official organ, CALIFORNIA AND WESTERN MEDICINE, that the reading of them be dispensed with.

Roll call showed thirty-eight delegates present, from Salt Lake, Weber, Boxelder, Uinta.

Moved by E. G. Hughes, seconded by John Z. Brown, that Eugene Worley and H. R. McGee be seated as delegates from Cache County. Unanimously carried.

The president welcomed the delegates, and then announced that the first order of business would be reports of the officers and committees. He then appointed the following Reference Committee: W. R. Calderwood, Salt Lake, chairman; E. P. Hills, Ogden, R. A. Pearce, Brigham City.

REPORT OF THE SECRETARY

As this convention convenes, we must pause for a moment and pay respect to the memory of our departed members during the past year, namely: Doctor Salathiel Ewing, Doctor John F. Critchlow, Doctor Ernest Van Cott, Doctor Patrick S. Keogh, Doctor M. R. Stewart—all of the Salt Lake County Society; Doctor Walter R. Emmett of Weber County, Doctor Herbert S. Pyne of Utah County, and Doctor Frederick Black of Boxelder County. The Committee on Necrology will prepare a suitable report, so that the memory of these departed will be transcribed in our transactions for this session.

As in the past two or three years, you will note that the speakers on our program are from outside the state. In many of our Council and committee meetings we have discussed plans for the annual conventions. It has seemed to us that talent from the outside makes a better meeting than mixing in one or two or three local papers, and it also eliminates little jealousies that are bound to creep in. I am sure the officers of this association will welcome comments from the House of Delegates on this matter.

The officers have visited all of the component county societies in this state during the past year, with the exception of Uinta and Carbon counties. Each society visited arranged for a program by the visitors, which included one scientific paper, a short talk from the president, and a report from the secretary on the last meeting of the secretaries of the National Association, and remarks from

members of the council. This was the usual program at all the meetings. The secretary recommends that these visits be continued and extended. Such visits furnish a good opportunity to get acquainted, as well as a stimulus to the component county society.

The membership this year, compared with last year, is as follows:

Boxelder 9, an increase of 1; Cache Valley 14, a decrease of 3; Carbon County 15, an increase of 3; Salt Lake County 224, an increase of 3; Uinta County 8, an increase of 3; Utah County 35, a decrease of 8; Weber County 41, same as last year. Total membership, 346.

During the past ten years our membership has increased nearly 40 per cent or a little less than one hundred members.

The following shows each year's membership, beginning with the year 1915:

Members—1915, 251; 1916, 248; 1917, 255; 1918, 252; 1919, 248; 1920, 291; 1921, 318; 1922, 316; 1923, 316; 1924, 347; 1925, 346.

I trust that by 1935 we may show a similar or greater increase for ten years.

In passing, I desire to congratulate Utah, and this association in particular, on having the best plan of any state in the Union for handling Industrial Compensation cases. You will have a detailed report from one of the members of the committee at this meeting.

I desire to call the attention of the House of Delegates to the lack of interest manifested by many of our members toward the journal of individual and community health, known as Hygeia. Only seventy-one physicians in this state care enough about the journal to subscribe for it; that is, less than one member in five. We are over 80 per cent delinquent in our educational endeavors to make this journal fight the battles of popular opinion before the great lay organizations. Can we expect to get a square deal before the public or before the legislature or before juries and courts if we neglect this great source of education? One of our members told me of a case in which a school teacher in this city used as her guide in teaching physical education to our children a sensational sex-exciting magazine. Then we wonder why the public flock to cults and faddists, and frequently turn a deaf ear to the physicians when they ask for just and fair treatment. We have an exhibit of Hygeia in the hall adjoining this lecture room where you who are not familiar with this magazine may examine it. I feel safe in saying that every progressive physician who is not a subscriber to Hygeia, who does not keep the current issue on his reception-room table, is failing to do his full duty to his patients and to the profession at large. This journal is published by your permission and at a loss which amounted to \$45,000 in 1924, which loss is paid for indirectly by you. Let us acknowledge our responsibility to the American Medical Association and increase our subscription from 71 to 347 in 1925 and 1926. We should go further and see that school teachers, public and school libraries in this city, at least, have this magazine available.

The subject of tax reduction at Washington is now being considered by President Coolidge and the various committees of our legislative bodies. Last year this and every other State Association protested to their various representatives and senators regarding the injustice of maintaining a \$3 tax on physicians' narcotic licenses and the injustice of not allowing physicians to deduct from their income tax the expense of attending medical conventions, and the expense of tuition, traveling, etc., in connection with post-graduate work.

The chairman of the Finance Committee in the National Congress is Senator Smoot of Utah. Senator King is also a member of this committee. The only state in the Union having two senators on the Finance Committee is Utah, so our responsibility is doubly that of other states. Well, you know what happened last year, when this thing was considered by the Finance Committee. They did not deny the justice of our cause, but only said they needed the money, so we are still paying.

Your present secretary recommends to the incoming president and new secretary that a special committee be appointed to call personally on Senators Smoot and King and discuss these matters and make a report to be filed

and embodied in these transactions, and that a copy be sent to the American Medical Association.

The secretary recommends to this body that the associate editor of CALIFORNIA AND WESTERN MEDICINE for Utah be reimbursed for postage and stationery used during the past year, and a small honorium be tendered him for his very excellent service to our Journal. And, further, inasmuch as the present secretary is going out of office and is not a candidate for re-election, I would recommend that the new secretary's salary be modestly increased and that a small monthly allowance be made to the secretary for stenographic service.

I desire to express my appreciation for the excellent support and advice that the members of this association have given me during the past eight years.

The following officers are to be elected: President-elect for one year; three vice-presidents for one year; secretary for three years; treasurer for one year; councilor for Third District, three-year term; councilor for Second District to fill the vacancy caused by the resignation of R. R. Hampton, which vacancy has been filled for several months by J. C. Landenberger.

All of which is respectfully submitted.

WILLIAM L. RICH, *Secretary*.

Upon motion duly made, seconded and carried, the report of the secretary was handed to the Reference Committee.

REPORT OF THE COUNCIL

As chairman of the Council, I desire to submit the following report concerning our association in general and draw your attention to some points of progress which should add encouragement to every member concerned. Without going into explicit detail which you shall hear from our treasurer, our association is in better financial condition than ever in its history.

There are fewer number of lawsuits pending or threatened against our members than was the case a year ago. This fact can be construed as evidence of the ethical progress we are making as an association and as individual members.

There are no complaints to make against any component society in our association, as there has been no infringement on the by-laws or articles of our constitution, and all business transacted by the various societies concerning their respective members and of new members applying for membership has been taken care of in a regular and orderly manner. The Council has been approached by one desiring membership in one of our local societies since you were last assembled, but this matter came up in an irregular way by the party concerned, and he was advised to make application direct to the society in which he desired membership. This was at a time when the society had discontinued its meetings for the summer, and up to the present, to my knowledge, no application has been filed with the local society concerning this individual's application. Had this matter come up in a regular way before the Council, in all probability this individual's attitude would have had to change materially before favorable action could have been taken.

The reason for this attitude on the part of the chairman of the Council is, that no good purpose can be served toward any individual seeking membership in our association with a wrong mental attitude bordering on slander and directed against our present membership. One of our first duties is protection of those who are with us, and any individual seeking admission by destructive means can serve no good purpose if admitted. We expect that all individuals applying for membership in any local society shall do so according to our by-laws and their applications disposed of promptly.

Since our last meeting R. R. Hampton submitted his resignation to the Council as the councilor member of the Central District on account of illness, which resignation was accepted, and J. C. Landenberger was appointed to fill the vacancy.

A member of the Utah County Society permitted his name to appear in an advertisement of Agmel. When his attention was drawn to the fact that it was unethical, he ordered withdrawal of his name and submitted a written apology for the offense.

Respectfully submitted.

E. G. HUGHES, *Chairman of Council*.

Councilor Hughes' report was handed to the Reference Committee.

REPORT OF COMMITTEE ON EDUCATION AND POST-GRADUATE WORK

FRANK B. STEELE, *Chairman*

(A combination or coalescence of the Committee on Scientific Work and the Committee on Education and Post-Graduate Work.)

Mr. President and Members of the House of Delegates—The work of your Committee on Education and Post-Graduate work has been rendered pleasant and less arduous by the cordial co-operation of the officers, the members of other committees, and members of the society not members of committees.

Our first endeavor was an effort to learn just what the members of the association wanted. To this end we invited suggestions and constructive criticism. Various ideas were presented. The outstanding complaints were from the members of the association living outside of Salt Lake County and from the eye, ear, nose, and throat specialists. The former complained that they could not afford to leave their practices and come to Salt Lake for a week for work which occupied them for only a couple of hours per day. The eye, ear, nose, and throat men complained that nothing in their line had been presented for three years, at either the association meeting or the Clinic Week.

With this information in hand, the president called a meeting of the officers at the Alta Club, to which the Committee on Post-Graduate Work and the Committee on Program were invited. This was in November. The gathering was turned into an experience meeting and general love fest, with the result that we resolved ourselves into a co-operative institution and decided to hold a combination association meeting and post-graduate course, giving an intensive week, covering as nearly as possible the entire field of medicine.

Then followed a long period of correspondence with men of national reputation in their various lines, and by about May 1 we had rounded out the program which, with some refinements, is now being presented to you. This, we believe, to be far and away the most pretentious offering ever attempted in this intermountain section. These men come at no expense to us, other than their entertainment while here, to give us freely of their knowledge and experience. Such a course, under other conditions, would cost much in time and money.

On the part of the committee, it is an experiment. If successful, we hope to see it repeated. If not, some other plan will have to be evolved.

President Kahn—Dr. Steele's report will be received and handed to the Reference Committee, and will then be placed on file and printed with the proceedings.

President Kahn further stated that Dr. McDermid, chairman of the Committee on Health and Public Instruction, was not present and no report had been received from his committee.

President Kahn also announced that the Advisory Committee on Hospitals had not turned in a report, and were not present at the meeting.

COMMITTEE ON INDUSTRIAL MEDICINE

A. A. KERR, *Chairman*

Mr. President and Members of the House of Delegates—I do not wish to make an extensive report. I have been under the weather for some time, as some of you know.

Our Committee on Industrial Medicine met with the Industrial Commission of Utah every week and adjusted claims, and saw patients and doctors. A great variety of cases were discussed. The Industrial Medicine work in Utah has assumed a large aspect and a great many cases are being taken care of by regular physicians, and a great many by corporations (through their doctors). The work at times has been quite heavy, but I think it has been handled quite satisfactorily.

COMMITTEE ON NECROLOGY

W. F. BEER, *Chairman*

Mr. President and Members of the House of Delegates—During the past year death has entered the ranks of our association several times, and has taken from us several of our members:

DOCTOR JOHN F. CRITCHLOW—Born September 24, 1857, at Tonawanda, New York. Died in an accident on July 24, 1924.

Dr. Critchlow came West with his parents in the early

70's. He spent his boyhood days in Eastern Utah. He attended the University at Rochester, New York, where he prepared for the study of medicine. He entered the medical department of the University of Pennsylvania, and was graduated from there in 1892. The next two years he spent in the German Hospital of Philadelphia. He then came West and located in Salt Lake City and practiced his profession here until 1898, when he joined the Utah Battery as a volunteer to go to the Philippines, in the Spanish-American War. Dr. Critchlow enlisted as a private, but rose to the rank of Captain of Battery B of Utah Artillery. On the return of the troop to Utah after the war, he was mustered out and resumed his practice of medicine and surgery.

He was elected a member of St. Mark's Hospital staff and served as an active and consulting member up to the time of his death.

Dr. Critchlow rapidly achieved prominence as a surgeon, and gained the respect of all his brother practitioners. His surgical opinion was respected by all who knew him.

At the time of his death he was division surgeon for the Western Pacific Railway; local surgeon for the D. & R. G. W. Railway, and for the Utah Fuel Company.

He was a past president of the Utah State Medical Association and also of the Salt Lake County Medical Society; and a member of the Masonic Order and the American College of Surgeons.

Dr. Critchlow is survived by his wife and two sons

SALATHIEL EWING, M. D.
1834-1925

DR. SALATHIEL EWING—The dean of Medical men of Utah.

Born in Union County, Ohio, on December 24, 1834. Died June 4, 1925.

As a boy he attended school in his home county. He was graduated from Sterling Medical College of Columbus, Ohio, in 1871.

At the outbreak of the Civil War, he became a minute-man, subject to the call of the Governor, David Todd of Ohio. He served under General Lew Wallace. He began the practice of medicine in Ohio.

In 1883 he came to Salt Lake, where he continued to practice his profession up to the time of his death.

Doctor Ewing was an active member of the Utah State and the Salt Lake County Medical Societies. He never was absent when it was possible for him to attend. He was the fourth president of the State Association and a

past president of the County Society; a Fellow of the American Medical Association. Since 1887 he served on the Utah Pension Board of Medical Examiners. He was a member of the Benevolent Protective Order of Elks, and was Exalted Ruler in 1911.

He was an ardent lover of children, horses, and dogs. The tribute that was paid him by one of the members of the profession explains fully the respect which all members of the medical profession who knew him held for him. This tribute is as follows:

"I pay tribute to one of our number who stands out pre-eminent in the medical body as an honest, conscientious, educated medical man—one who has always been a leader in his profession, up to the moment, grasping every true advance, every new thought worth keeping, always ready with helping advice; a safe and wise consultant and an all-around good doctor; a parliamentarian of the first order, and a guiding spirit in all our society deliberations—always able in debate to stoutly defend his position; kindly and courteous to his opponent, but resolute and fearless in standing for the right."

"Dr. Ewing has taken his place at the head of all our societies, and when not holding an office has been one of the strongest floor workers, ready in debate or discussion, and a frequent contributor to scientific literature. He has never missed a state meeting, and has always been at the front in any scientific gathering.

"Loved his profession.—This was a beautiful world to him. He has enjoyed every moment, consequently he has not run counter and has not had the hard buffeting of the reformer or the ascetic. He loved his profession, respected his patient as one needing kindly aid and counsel. He has lived in our community for many years, and has always had the profound respect and love of all the people. He is an example of the Highest type of American manhood in the medical profession."

Dr. Ewing was buried in Mt. Olivet Cemetery on June 7, 1925, under the auspices of the Salt Lake Lodge No. 85, B. P. O. E.

DOCTOR ERNEST VAN COTT—Born December 18, 1875, at Salt Lake City. Died August 27, 1924.

Doctor Van Cott was one of Salt Lake's foremost physicians. He had been associated with the medical department of the O. S. L. Railroad since 1904. He was graduated from Rush Medical College in 1903.

Dr. Van Cott had been on a vacation to Yellowstone National Park, and while on his way home he dropped dead from heart disease.

DOCTOR MURRAY ROCKWELL STEWART—Born in Indiana September 8, 1868. Died February 5, 1925.

When a boy Dr. Stewart came West and worked for the O. S. L. at McCammon, Idaho, and later for the D. and R. G. at Ogden, Utah. While working at Ogden, Utah, he began the study of medicine. He finally entered Rush Medical College of Chicago, Illinois, and was graduated in 1898.

For six years he was City Physician under the American party administration, and for three years served as a member of the State Land Board, under Governor Bamberger.

Dr. Stewart was a member of the Masonic fraternity and belonged to the Apollo Commandery of Chicago, the Weber Lodge No. 6, Masonic Order at Ogden, a member of El Kalah Shrine, Salt Lake. He was a member of the Utah State Medical Association, the Salt Lake County Medical Society, and the Chamber of Commerce. He was elected a member of the City Commission more than three years ago, and was head of the Department of Parks and Public Property.

His parents are both dead and the only surviving relative is his widow.

DOCTOR SEYMOUR B. YOUNG—Born at Kirtland, Lake County, Ohio, on October 3, 1837. Died December 13, 1924.

Graduated from the University of New York in 1874. He practiced his profession here in Salt Lake City continuously since his graduation.

He was among the earliest practitioners of this state, being one of the charter members of the Salt Lake City Medical Society, which was arranged and organized at

the home of Dr. J. M. Benedict. The doctors present at that time were Doctor W. F. Anderson, Dr. Hamilton, Dr. Williamson, Drs. J. M. and Denton Benedict, Dr. Standish, Dr. McClain, Dr. J. S. Richards, Dr. Heber John Richards, and a few others, all of whom have long since died. He was a member of the G. A. R. in 1863-64. He saw service against the Digger Utes in Tooele County and Cedar Mountains in 1866. He was in the expedition to San Pete and Sevier counties in the Black Hawk War. He was a member of John Quincy Knowlton Command, and Junior Vice-Commander of that Post.

Dr. Young was a devout member of the L. D. S. Church, and at one time filled a mission. He was a member of one of the oldest pioneer families.

DOCTOR EDWARD PALMER LECOMPTE—Born in Cambridge, Massachusetts, May, 1846. Died July 26, 1924, in Park City, Utah.

He entered the Army in 1874 as Army Surgeon, and came to Salt Lake to be stationed at Fort Douglas in 1876. Previous to coming here he served with General Custer under the colors until 1882. He went to Park City in 1883.

He was buried in Mt. Olivet Cemetery, Salt Lake City. He is survived by two children, Mrs. W. I. Snyder and Dr. E. D. Le Compte of Salt Lake City.

DOCTOR HERBERT SAMUEL PYNE (Utah County Medical Society)—Born February 12, 1862, at Norfolk County, England. Died at Provo, Utah, September 14, 1924.

In 1873 he came to Utah; in 1886 he engaged in the drug business. He began the study of medicine at the Washington University, graduating in 1908. He lived continuously, after graduation, in Provo, where he practiced his profession. He was a member of the State Medical Association and of the Utah County Medical Society, and a Fellow of the American Medical Association. He was an active member of the L. D. S. Church. He was buried in the city cemetery at Provo.

DOCTOR FREDERICK A. BLACK—Born in 1894. Died at Garland, Utah, on September 15, 1924.

Graduate of the Western Reserve University.

DOCTOR A. W. BURROWS—Born in Manchester, England. Died October 16, 1924.

Graduate of the P. and S., Chicago.

Came to Utah in 1889. Practiced his profession in this city from the time he came here in 1889 until the time of his death.

(See report of Reference Committee.)

DOCTOR P. S. KEOGH (Salt Lake County Society and Utah State Medical Association)—Born in 1850.

Dr. Keogh had been an "age limit" member of our association for several years. He was graduated from Bellevue in 1885, and was licensed to practice in Utah in 1896.

DOCTOR W. R. EMMETT (Weber County Medical Society and Utah State Medical Association)—Born in 1875. Died March 23, 1925.

Was a graduate of Northwestern in 1910, and began his practice in Utah that same year. Dr. Emmett was prominent in the Weber County Society.

Dr. Kahn—Dr. Beer's report will be received and turned over to the Reference Committee.

President Kahn announced that Dr. Landenberger was out of the city and that no report had been received from the Committee on Professional Welfare and Ethics.

CONFERENCE COMMITTEE ON INDUSTRIAL MEDICINE

S. D. CALONGE, *Chairman*

MEDICAL PROBLEMS UNDER INDUSTRIAL COMPENSATION LAWS

With the exception of laws regulating medical practice, no legislative acts have had more direct effect upon the physician than the Workman's Compensation laws in force in the different states and professions of the United States. More responsibility rests upon the physician than upon the employer, employe, or insurance carrier, and greater restrictions are placed upon him than upon all the other three primarily interested parties.

The employer's interest lies in securing proper medi-

cal care for the injured employe and payment of compensation for lost time and bodily injury, together with immunity from damage suits such as were common before this law became effective.

The employe's interest lies in securing proper medical attention and just compensation for his lost time and his injury.

The insurance company's interest lies solely in reducing the cost of such benefits to employer and employe to the lowest possible figure in order that larger profits to their companies may be gained.

Upon the physician rests the greater responsibility of restoring the injured workman to as nearly 100 per cent efficiency as possible in the shortest time and for the minimum fee. He must meet not only the demands of the patient, but of the employer, the insurance company, and the Industrial Commission or Compensation Bureau. He must render this service for a fixed fee without consideration of the financial ability of the insurance company to pay fees which would be obtained in like cases in private practice. This fixed fee is in most states set by legislators or boards who have no knowledge of medical and surgical problems. (In Utah we are more fortunate, as we will later explain.)

Unlike the employer, the physician is not relieved from the worry and annoyance of damage suits, but statistics show that during the past eight years these suits against physicians have increased more than 100 per cent as a direct result of this law. Thus, is the physician penalized for failing to restore to 100 per cent efficiency the workman who may have been injured through gross carelessness on the part of himself or his employer.

In only eight states do physicians receive fees for such services which are equal to fees for private practice. These are mostly Western states. In seventeen states, chiefly New England and Southern states, two to four weeks' care for injured employes is provided with a maximum of \$100 to \$150 for all hospital and medical care.

Dr. B. L. Bryant states that in Maine a few years ago the insurance companies put their cases in the free wards of hospitals, where staff physicians were obligated not to charge for their services.

It took the combined action of physicians, hospital boards, and the Commission to correct this unfair situation.

In Oregon a determined attempt has been made to establish socialistic medicine by a plan under which the Commission could establish hospital and medical contracts and every citizen have such care in illness or accident under state insurance. This was defeated only after a bitter fight, and the question is alive in several states today and it behooves medical men to resist it wherever it is placed before legislatures.

In Washington a medical adviser is appointed to the Commission at a salary of \$5,000 per year. He is, in fact, a medical supervisor of all doctors in the state and arbitrarily says who may or may not treat industrial cases.

You can readily see how much trouble may arise out of such a situation where the advisor may be governed by political powers, as is the case in nearly all appointive positions.

In Pennsylvania a case is now in the Supreme Court, testing a ruling of the chairman of the Compensation Board in 1919, that under the law the hospital should receive its fee for ward cases, but that the physicians of the staff could not make a charge for services to such cases.

In Utah, before co-operation between the Medical Association and the Industrial Commission was established, a radical element advocated that physicians receive \$1 per hour for services in industrial cases and furnish all materials used. This move was blocked by the Commission at that time. The spirit of antagonism between medical men and the Compensation Commissions, which at first seemed general, is giving place to broader views and better understanding of the rights of all concerned, and the tendency is justice toward all.

The greatest danger to the medical men as a whole is the tendency of commissions, employers, and insurance companies to assume the right to dictate to an employe what physician he shall employ instead of giving to every individual the right to choose his own physician, which

was one of the first principles of justice upon which the law was based.

In many states, including ours, welfare associations, established by men of keen business ability who are not physicians, are operating. These associations contract for the care of the sick and injured in mining camps and country communities and hire newly licensed physicians for inadequate salaries to do the work.

Fees of the physician for compensation cases go to the association, and the promoters take the profit from the doctor's work. This is a vicious plan which should be fought wherever found and wiped out in every state.

Among the unsolved problems before commissions and medical advisers, we find:

Traumatic neurosis, which at present is applied by claimants and attorneys to every condition, from tingling sensations to epilepsy and total paralysis. Some definite limitation of these malingerers and ambulance-chasing attorney's "stock claim" must be determined by our profession in order that compensation boards may deal intelligently with this condition.

Another question which has caused much controversy among the eye and ear specialists of our state is the lack of uniform tests or scale upon which partial loss of sight or hearing can be based. Estimates on both sight and hearing defects have varied from 10 per cent to 90 per cent in the same case, and left the Commission entirely at sea in adjusting the claims.

The relation between recent injuries and long-standing pathological conditions in regard to ultimate disability is one of the most difficult problems before medical advisers and industrial commissions.

The question of typhoid fever being a compensable condition when contracted under conditions where employes had but one source of water supply, and this proved to be contaminated, is now before the Utah Commission for their decision. Also the question of accidental lead poisoning is another problem which they are called upon to solve. These particular conditions are of great interest to the medical profession, and will have far-reaching effect upon industrial insurance in the state of Utah, according to the decision rendered in the cases by our present Commission.

The close co-operation between the Industrial Commission and the Medical Association of our state has eliminated most of the objectionable features of which we have spoken, and the head physician of one of the largest insurance companies of the United States who recently investigated the industrial compensation conditions in all states said, after attending a session of the Medical Advisers and Industrial Commission, that Utah has the most satisfactory working plan of any state in the Union. For the benefit of those who may not be acquainted with this plan, I will state that:

The Industrial Commission allows fees which obtain in private practice in Utah, and that the State Medical Association appoints a board of three medical advisers who serve without pay and who meet each week with the Commission, examine all cases in question, and give any needed advice as to the further treatment, disability, fees charged, etc. By this method politics is kept out of the medical part of the Commission's duties.

We believe that each state medical association should have a standing committee to investigate and report on all matters affecting the medical profession which may arise under the administration of Industrial Compensation laws.

The president of our State Association has requested me to urge upon all physicians of Utah the importance of the Medical Advisers' work and remind them that those appointed for this service should give it their earnest attention, as through this committee as a whole the entire profession of the state is constantly represented before the Industrial Commission, and all questions justly and amicably settled. Some doctors appointed have failed to attend meetings. Every doctor appointed on this committee should not fail to attend the meetings with the Commission or notify the chairman of the committee twenty-four hours before, if he cannot. If we lose interest, then all that our profession has gained under this plan will be lost and some less desirable plan will be put in operation.

(Dr. Calonge's report was read before the General Assembly.)

The following resolution was presented by F. H. Raley:

WHEREAS, At the meeting of the House of Delegates last year our president called your attention to the importance of helping to defray the expenses of our delegate to the meeting of the American Medical Association; and

WHEREAS, The following representative states either give their delegates \$100 or more toward defraying their expenses, or pay their railroad fare and Pullman fare over a direct line to the place of meeting and return: Connecticut, South Dakota, Massachusetts, New York, Illinois, Nebraska, North Dakota, Wisconsin, Michigan, Montana, and Tennessee.

BE IT RESOLVED, That we appropriate the railroad and Pullman fare to and from the convention city to help defray the expense of the delegate each year to the annual meeting of the House of Delegates of the American Medical Association.

The president announced that the resolution would have to be handed to the Reference Committee first; then acted upon, and if agreeable would be presented to the House of Delegates for their action at a later meeting.

Meeting adjourned to convene at 5 p. m., or immediately after the afternoon scientific session.

SECOND SESSION—HOUSE OF DELEGATES UTAH STATE MEDICAL ASSOCIATION

The House of Delegates convened at 5 p. m. September 7, 1925, the president, Sol G. Kahn, presiding. Roll call showed thirty-five delegates present.

Doctor Kahn announced that, inasmuch as the legislature did not meet this coming year, the Committee on Public Policy and Legislation had not been active, and Doctor Straup had not sent in any report. This also applied to the sub-committee on Public Policy and Legislation.

REPORT OF THE DELEGATE TO THE AMERICAN MEDICAL ASSOCIATION MEETING

DR. E. M. NEHER, *Delegate*

Report of the proceedings of the Seventy-sixth Annual Session of the House of Delegates of the American Medical Association, held at Atlantic City, May 25 to 29, 1925.

We regret we were unable to attend this meeting in person, and the data for this report has been obtained from the official minutes of the meeting of the House of Delegates.

While the registration was not as large as at the Chicago meeting—less than 5000 this year, as compared with over 8000 a year ago—it was reported as the best in many ways of any of the meetings ever held. Nine physicians were registered from Utah.

The addresses of the Speaker of the House of Delegates, F. C. Warnshuis; of the president, William A. Pusey; and of the president-elect, William D. Haggard, were interesting, as they sounded the "keynote" of the policy of the association.

Speaker Warnshuis advised that the by-laws be amended so that the secretary for the association be elected by the Board of Trustees instead of by the House of Delegates. However, the House of Delegates did not consent to this change. He also advised, whenever possible, resolutions relative to the policy of the association should be submitted to the secretary at least thirty days previous to the time of the meeting of the House of Delegates, in order that a copy of the proposed resolution might be sent to each delegate for his deliberate consideration.

President Pusey gave his valedictory, enumerating some of the pleasant duties of the president, as his reception at many state associations and meetings with the Board of Trustees. He admonished the delegates of their very important position and urged them to do their duty.

President-elect Haggard deplored the long course of study for the medical student, and suggested it might be shortened at least one year in the high school course. He urged the delegates to see that medical practice laws of their states required the same preliminary education of all who treat the sick. Each state association should be alert to any bills introduced in either their state legislature or congress, which are derogatory to the profession. Malpractice suits should be carefully studied, and if found to be fraudulent suits, fought to the end. If fraud can be traced to any member of the bar, report such

fraud to the Bar Association. He also made some pertinent suggestions relative to the Industrial Commissions. Every case coming within their jurisdiction is a medical case, and yet only fifteen of the forty-two states with compensation laws have a physician connected with their administration board. He advises:

1. A medical director attached to each Commission.
2. A consulting staff of specialists on a fee basis.
3. Examining physicians on a fee basis.

Every injured patient should have the right to choose his surgeon, and the denial of this right is non-American.

He took to task the Veterans' Act granting Government hospitalization of all persons who served in any war since 1897, without regard to their disability or financial circumstances. It requires only one more step to include the families, and we have state medicine. If the Government wishes to care for its soldiers, this should be done at home with the family physician attending, among friends, and not shifted away to some distant Government hospital.

The Reference Committee approved the address of the president-elect.

Report of the Secretary—The secretary, Olin West, reported 90,646 members of the American Medical Association, a net gain of 590. Our state has 505 physicians listed in the ninth edition of the directory, with 356 as members of the association.

Report of the Trustees—The report of the trustees showed 85,536 subscribers to the Journal, an increase of 4500 during the year. Utah has 320 subscribers, or about 64 per cent of the registered physicians. The total receipts of the Journal pass the one million dollar mark. The sale of the advertising space, amounting to six hundred thousand, being the largest item.

"Hygeia" is produced at an annual loss of over \$40,000. It is steadily gaining subscribers, having passed the thirty thousand mark. Our state records show 71 physicians and 126 laity subscribers.

The following are some of the resolutions passed by the House of Delegates:

1. Resolution from the Section of Ophthalmology, naming a standard percentage of compensation for all eye injuries and disfigurements of the face.
2. Resolution of physical standards for drivers of motor vehicles. The applicant must have not less than 20/50 in one eye and 20/100 in the other eye, with or without glasses.
3. Resolution approving the report of the Judicial Council, condemning Life Institute and periodic health examinations by commercial organizations. They urge that health examinations be made by the family physician and advise the patient of his physical condition direct. They declared that every member and Fellow of the association should "Live up to the spirit of the Council."
4. A resolution declaring for the abolishment of the tax on physicians under the Harrison Narcotic Act, as was also one favoring the deduction from income tax returns of travel expense incurred in attending meetings of medical societies and post-graduate study.

The following officers were elected for the ensuing year: President-elect, Wendell C. Phillips; vice-president, Phillip Marvel; secretary, Olin West; speaker of the House, Fred Warnshuis.

Joseph Pettit of Oregon was elected to fill the unexpired term of the late trustee, Dr. W. T. Williamson.

Dallas, Texas, was selected as the place of meeting for 1926.

Dr. Neher's report was turned over to the Reference Committee for their action and report.

ARRANGEMENTS COMMITTEE

DR. H. P. KIRTLEY, *Chairman*

Dr. Kirtley reported verbally to the effect that his committee had worked in conjunction with Dr. Steel's Committee on Education and Post-Graduate Work, and Dr. Goeltz's Committee on Scientific Work—all of which committees had combined into one to make the convention a success; that the banquet had been arranged for and would be held at Hotel Utah on the evening of the 8th; that all indications pointed to its success; that the doc-

tors by the end of the week would be able to tell exactly how the Arrangements Committee had functioned. Dr. Kirtley referred to the splendid co-operation of the University of Utah and especially the president, Dr. George Thomas, who had done so much to make the meeting a success.

President Kahn announced that there had been nothing for the Transportation Committee to do in particular, therefore Dr. Benjamin, the chairman, did not feel it necessary to make a report.

Dr. John Z. Brown—In looking over the program, I have been wondering if we could not do away with some of our committees—if we could not do something to reduce the number of committees; arrange the work in some way so there will be less time taken up in the House of Delegates in the reading of the reports. If we could have fewer committees and authorize those committees to call on helpers, I think the work could be minimized.

Secretary Rich—Three or four of the committees were appointed temporarily to help out during the year in which they were appointed; for instance, the sub-committee of Public Policy and Legislation. It was needed at the time it was appointed, and there was plenty of work to be done, but it has not been necessary this year. There are some committees that do not function. The Committee on Hospitals has not done much for two or three years. There are committees that the association asks us to keep and to appoint them for one, two, three, four, and five years. We could do away with three or four committees very well next year.

President Kahn—Which committees, Dr. Brown, do you think could be eliminated?

Dr. Brown—I have not gone over them carefully—merely offered that as a suggestion. When the legislature does not meet, we do not need that committee nor the sub-committee.

President Kahn—Something might come up at some time that would require the attention of a committee that is not particularly active. And in the meantime, they get honorable mention, even though they do not put forth any particular effort.

Has anyone else anything to offer?

Dr. Goeltz, chairman of the Committee on Scientific Work, stated that his committee had worked in conjunction with Dr. Steel's committee, and, therefore, he had nothing to report that was not embodied in Dr. Steel's report.

President Kahn announced that the Medical Department University of Utah Advisory Committee would not report; that the work of this committee had been touched upon by the secretary, and would be included in the president's report.

Dr. Homer Rich of Vernal—We have a physician out in our locality who will be 101 years old this fall. He is, so far as we know, the oldest physician practicing in the United States. I think it would be fitting if any of us reach that age and are still kicking that some little recognition be given us. I should like to see some little mark of recognition given Dr. Harvey Hullinger. He received the Northwest Medicine complimentary for a number of years. He is an honorary member of our society. We have not reported him as a member of the State Association, but we should like some mark of recognition given him on account of his great age and still being in good physical condition.

President Kahn—I suggest, Dr. Rich, that you prepare a resolution to present at the noon meeting of the House of Delegates tomorrow; then we can act upon it.

Dr. John Z. Brown—I move we adjourn. Seconded and carried.

THIRD SESSION OF THE HOUSE OF DELEGATES

Held at 12 o'clock noon, Tuesday, September 8, 1925, at the University of Utah, President Sol G. Kahn presiding.

President Kahn announced that the first order of business was the election of officers, but that several reports that should have been given at previous meeting could now be presented if the House were willing.

Moved by E. C. Hughes that said reports be given. Seconded by T. A. Flood, and unanimously carried.

REPORT OF THE COMMITTEE OF THE
OFFICERS' RESERVE CORPS

Dr. R. J. ALEXANDER, *Chairman*

The committee of the Officers' Reserve Corps, on completing its function under the present administration, has the following report to make:

It is with great satisfaction that we inform the members of the State Association that of all the states in the Ninth Corps Area Utah has the highest percentage of its medical men enrolled in the Medical Reserve Corps. This is 14 per cent. The state that stands next in the list has only 10 per cent of its physicians and surgeons as members of the Reserve. When one considers that the states of Washington, Oregon, California, Nevada, Idaho, and Montana comprise the Ninth Corps Area, as well as our own state, and that the total number of our medical brethren in this state is 505, certainly we can derive great satisfaction and gratification in the showing that we have made as members of the Officers' Reserve.

The above figures are those compiled by Colonel Munson of San Francisco, the surgeon of the Ninth Corps Area.

At the recent encampment of the 104th Division which was held at Camp Lewis from August 2, 1925, to August 16, 1925, the skeleton personnel of the 329th Medical Regiment was ordered out for training. Included in this were Captains A. Blumberg, L. J. Paul, and Charles F. Wilcox Jr., all of this city. They spent a most interesting two weeks on courses that included ambulance and station hospital work, theoretical and practical epidemiology, map-reading, and terrain work, as well as medical administrative work.

In conclusion your committee would like to impress on the members of the medical association that it is the duty of every man to become a member of the Medical Reserve Corps. We feel that at least 50 per cent of our membership should hold a commission in the Reserve. The chairman of your committee possesses all of the application papers necessary and will gladly assist anyone who may so desire to join. The committee would also suggest that during the ensuing year the new committee that is appointed be allowed a small sum for stamps and paper so that every physician and surgeon residing in our state can be communicated with directly and shown the duty and obligation that he owes his flag, as well as the actual good that he will receive through membership in the Reserve.

Dr. Alexander's report was handed to the Reference Committee.

REPORT OF THE TREASURER

T. A. FLOOD, *Treasurer*

Period June 20, 1924, to September 8, 1925

Receipts

Cash in National Copper Bank checking account, June 20, 1924.....	\$3,353.66	
Delinquent dues received from component societies	112.00	
Dues from component county societies for current year, received between June 20, 1924, and September 8, 1925, the following:		
Salt Lake County.....	\$1,106.50	
Cache	70.00	
Carbon	75.00	
Boxelder	45.00	
Uinta	40.00	
Utah	175.00	
Weber	210.00	1,721.50

Total receipts in checking account.....\$5,187.16

Disbursements

California and Western Medicine—		
1925 subscriptions	\$706.00	
1924 subscriptions	688.00	\$1,394.00
A. M. A. Directory.....		12.00
Entertainment of guests at the Logan meeting (1924), including hotel bills, entertainment, etc.		204.85
Operation of movie machine and drayage thereon, Logan meeting		17.20

Stationery and printing, including programs, preliminary notices, etc.	183.75	
Stenographic work, report of Logan meeting, postage, and copying of medical testimony for Welfare Committee	373.23	
Floral bills	64.50	
Salary and expenses—secretary	207.79	
Councilor's expenses—traveling, etc.	125.00	
Total expenditures	2,582.32	

Total in checking account at National Copper Bank\$2,604.84

Savings Account

Amount in National Copper Bank Savings Account, No. 18,973, on June 20, 1924.....	\$1,197.62	
Oct. 1. Interest on savings account	\$ 11.97	
Oct. 1. Interest on savings	24.18	
Nov. 24. From the Committee on Post-Graduate Work, Dr. H. L. Marshall.....	177.56	
Apr. 1-25. Interest on savings account	27.01	
July 21, 1925. Bond coupons	12.75	253.47
Sept. 8, 1925. Amount in savings account		1,451.09
Total in both accounts.....		\$4,055.93

I also carry for the association three \$100 bonds of the second Liberty Loan with coupons attached thereto, from November, 1925, to November 1942.

I hereby certify that I have checked all the records and accounts of the Utah State Medical Association, including the checking and savings account of the Utah State Medical Association for the year June 20, 1924, to and including September 21, 1925, and that the account as stated on the foregoing page is correct. I further certify that I have verified the bank accounts (both savings and checking accounts with the National Copper Bank) and have checked the Liberty bonds mentioned on said report, and find them to be exactly as stated on said report of Dr. T. A. Flood, treasurer.

LEONA D. BILLINGS, *Auditor*.

President Kahn—You have heard these two reports. They will both be turned over to the Reference Committee. However, where the expenditure of money is concerned (as suggested in Dr. Alexander's report), that matter would have to be handled by the Council. It could be referred to them with power to act.

D. L. Barnard moved that the matter of the expenditure referred to in Dr. Alexander's report be referred to the Council with power to act. Seconded and carried unanimously.

REPORT OF THE REFERENCE COMMITTEE

W. R. CALDERWOOD, *Chairman*

Your Reference Committee beg leave to report as follows:

We approve the recommendation of the secretary for the appointment of a committee to confer with Senators Smoot and King, with reference to the Harrison Narcotic Drug Act; also the elimination from the income tax report of the expense incurred in traveling to medical conventions and in pursuing post-graduate work.

We recommend, in connection with the statement made by the secretary, that the salary of the incoming secretary of the Utah State Medical Association be fixed at \$250 and necessary expenses.

We approve the recommendation of the secretary that physicians lend their aid and support to the magazine "Hygeia," not alone that they place it on their office tables, but that they advise their patients of the value of this magazine.

We also approve the recommendation of the secretary

that the Utah associate editor of the California and Western Journal of Medicine be allowed a fee of \$50 and necessary expenses for postage, stationery, and stenographic help.

We compliment the Committee on Education and Post-Graduate Work and those who co-operated with them in formulating our program for this year. We feel that it is a distinct step in advance.

We endorse the resolutions and recommendations offered in the report of the delegate to the A. M. A., and compliment the Council for the splendid condition of co-operation among the members of the component societies.

We compliment Dr. Beer on his report on necrology, and beg to add the names of P. S. Keogh of Salt Lake and W. R. Emmett of Ogden. Dr. Keogh was born in 1850 and had been an "age limit" member of our association for several years. He was graduated from Bellevue in 1885, and was licensed to practice in Utah in 1896. Dr. Emmett died on March 23 of this year. He was born in 1875, and was a graduate of Northwestern in 1910. He began his practice in Utah that same year. He was a member of this association and also of the Weber County Society.

We approve the following resolution offered by Dr. Raley, and suggest its adoption:

WHEREAS, At the meeting of the House of Delegates last year our president called your attention to the importance of helping to defray the expenses of our delegate to the meeting of the American Medical Association; and

WHEREAS, The following representative states either give their delegates \$100 or more toward defraying their expenses, or pay their railroad fare and Pullman fare over a direct line to the place of meeting and return: Connecticut, South Dakota, Massachusetts, New York, Illinois, Nebraska, North Dakota, Wisconsin, Michigan, Montana, Tennessee; be it

RESOLVED, That the Utah State Medical Association appropriate the railroad and Pullman fare to and from the convention city to help defray the expenses of the delegate each year to the annual meeting of the House of Delegates of the American Medical Association.

We also approve the following resolution which was offered by the secretary yesterday and suggest that it also be adopted by this body:

BE IT RESOLVED: By the Thirty-first Annual Session of the House of Delegates of the Utah State Medical Association now in session:

That this association protests and is opposed:

First. To a continuance of the \$3 Harrison Narcotic tax. Prior to the war the tax for a physician's narcotic license was \$1. This tax was increased to \$3, as a war measure. The law was enacted for the protection of the general public, and the cost of administering it should be paid for out of the public fund and not by increasing the physician's tax. We want a return to the normal tax.

Second. Regarding the interpretation by the Tax Commissioner of non-deductible items of expense in computing a physician's income tax:

(a) Such as expense of traveling to and from medical conventions for educational purposes.

(b) Expense incurred in the pursuit of post-graduate study.

Under the last two headings the treasurer's office at Washington has ruled that a physician may not, when computing his income tax, deduct such items from his income tax as noted above. In the general scheme of tax reduction, now under consideration, this association feels the injustice imposed by such interpretation, and is anxious for consideration and relief at this time.

We approve the report of the treasurer, and concur in the report of R. J. Alexander and suggest that the matter of the small appropriation asked for in Dr. Alexander's report be referred to the Council.

T. C. Gibson moved the adoption of the report of the Reference Committee, with the exception of those matters pertaining to the expenditure of money, which matters, under the constitution, have to go to the Council. Seconded by John Z. Brown.

The secretary suggested that Dr. Gibson include in his motion the adoption of the two resolutions contained therein, without rereading the resolutions. Dr. Gibson,

therefore, reworded his resolution accordingly. It was again seconded by Dr. Brown, and unanimously carried.

The president announced that election of officers would be the next order of business.

Roll was called by the secretary, showing the following number of delegates present:

Cache Valley, 2; Salt Lake, 20; Utah, 1; Weber, 4; Uinta, 1; Boxelder, 1; Carbon, 0.

It was moved by D. L. Barnard, seconded, and carried, that F. J. Curtis, an alternate delegate of Salt Lake City, be seated in place of L. N. Ossman, who was not present. Seconded by Dr. Baldwin, and carried, and thereupon Dr. Curtis was seated as a delegate, making thirty delegates in all voting.

The president appointed M. M. Critchlow and G. E. Christensen as the tellers.

Secretary Rich announced that the president-elect, T. C. Gibson, would be the president this coming year. That the following officers were to be elected:

President-elect, first vice-president, second vice-president, third vice-president, secretary (three-year term), treasurer, councilor Third District (three-year term), councilor Second District (two years).

President-elect—John Z. Brown nominated W. R. Calderwood of Salt Lake City. Motion seconded by M. M. Critchlow.

Dr. Baldwin—I move, Mr. Chapman, if there are no other nominations, that the nominations close; that the rules be suspended and that the secretary be instructed to cast the unanimous vote of the House of Delegates for W. R. Calderwood for president-elect for the coming year. Motion seconded by G. F. Roberts, and unanimously carried. Thereupon the secretary cast the unanimous vote of the House for Dr. Calderwood, and the president announced that W. R. Calderwood would be the president-elect for the ensuing year.

First Vice-President—Frank K. Bartlett of Ogden was nominated by E. P. Mills.

Dr. Mills—If there are no more nominations, I move that the nominations close; that the rules be suspended and that the secretary be instructed to cast the entire vote of the House for Frank K. Bartlett of Ogden for first vice-president for the coming year. Motion seconded by E. C. Rich, and unanimously carried. Thereupon Secretary Rich announced that Frank K. Bartlett was the first vice-president for the coming year.

Second Vice-President—Homer Rich of Vernal was nominated by A. A. Kerr. Seconded by E. M. Neher.

Dr. Steele—I move that the nominations close; that the rules be suspended and that the secretary be instructed to cast the vote of the House for Dr. Rich of Vernal as second vice-president of the Utah State Medical Association for the ensuing year. Motion seconded by C. L. Shields, and carried unanimously. The secretary thereupon cast the unanimous vote of the House for Dr. Rich as second vice-president, and the president announced that Dr. Homer Rich would be the second vice-president for the coming year.

Third Vice-President—L. W. Oaks of Provo was nominated by G. E. Christensen. Motion was seconded by Eugene Smith.

Dr. Calderwood moved that the rules be suspended and that the secretary be instructed to cast the vote of the House for L. W. Oaks of Provo as third vice-president. This was done, and the president announced that Dr. Oaks was elected third vice-president of the association for the coming year.

Secretary—S. C. Baldwin nominated F. B. Steele of Salt Lake. Nomination seconded by E. C. Rich. Edward Le Compte nominated Edward D. Le Compte of Salt Lake. Nomination seconded.

Ballot was taken, with the result that Dr. Steele was elected.

Thereupon the president announced that F. B. Steele would serve as secretary of the association for the coming three-year term.

Treasurer—While the ballots on the secretary were being taken and counted, Dr. John Z. Brown moved that the man who did not get the secretaryship—Dr. Steele or Le Compte—be elected as treasurer.

Motion seconded and carried unanimously.

When the result of the ballot for secretary was announced, Dr. Brown again moved that the unanimous

vote of the House of Delegates be cast for Edward D. Le Compte as treasurer of the association; that the rules be suspended.

Seconded by George F. Roberts, and carried unanimously.

Thereupon the secretary cast the vote of the House for Dr. Le Compte as treasurer, and the president announced that Dr. Le Compte would serve as treasurer for the coming year.

Councilor Third District (three-year term)—E. G. Hughes of Provo was nominated by George F. Roberts. Nomination seconded by F. B. Steele, who further moved that the rules be suspended and that the secretary be instructed to cast the vote of the House for E. G. Hughes as councilor of the Third District for three-year term. Motion seconded by F. J. Curtis, and carried unanimously.

Thereupon the secretary cast the vote of the House for Dr. Hughes, and President Kahn announced that Dr. Hughes would again serve as councilor from the Third District for the next three years.

E. G. Hughes announced that a vacancy had occurred in the Council this last year through the resignation of R. R. Hampton, and that J. C. Landenberger had been appointed to take Dr. Hampton's place for the balance of the year. That it would be necessary to elect Dr. Hampton's successor. He moved that J. C. Landenberger be appointed councilor, or elected councilor from the Second District, to fill the vacancy occasioned by the resignation of R. R. Hampton, Dr. Landenberger to serve for the next two years. Motion seconded by D. L. Barnard, and unanimously carried.

G. E. Christensen moved that Dr. Landenberger be elected by acclamation. Seconded and carried.

Whereupon the president announced that Dr. J. C. Landenberger would serve as councilor from the Second District for the ensuing two years.

The secretary then announced that the officers for the coming year were as follows:

President, T. C. Gibson, Salt Lake City; president-elect, W. R. Calderwood, Salt Lake City; first vice-president, Frank K. Bartlett, Ogden; second vice-president, Homer E. Rich, Vernal; third vice-president, L. W. Oaks, Provo; secretary (three-year term), Frank B. Steele, Salt Lake City; treasurer, Edward D. Le Compte, Salt Lake City; councilor First District (unexpired term) one year, W. LeRoy Smith, Brigham City; councilor Second District (two more years to serve), J. C. Landenberger, Salt Lake City; councilor Third District (three-year term), E. G. Hughes, Provo; delegate to A. M. A. (one-year term, unexpired), E. M. Neher, Salt Lake City; alternate delegate to A. M. A. (one-year term, unexpired), A. C. Behle, Salt Lake City.

The president announced that the place of meeting for the 1926 meeting was the next order of business.

F. H. Raley moved that the 1926 meeting be held in Salt Lake City. Seconded by J. P. Kerby, and unanimously carried.

E. G. Hughes—I have been in close touch with the work of this association for the past few years, and also with the work of Dr. Rich, our outgoing secretary. Dr. Rich has served this association as secretary for the past eight years, and this association has very much to commend in him for the untiring efforts that he has put forth in acting as our secretary. I am sure I am expressing the heartiest thanks of the members of this association when I express to Dr. Rich the sincere appreciation of our membership for his splendid work. He has worked faithfully and diligently to carry out the work of the association, has upheld their ideals, and the work accomplished has been all we could expect. I make a motion that we extend to Dr. Rich a vote of thanks for the work that he has done. Motion seconded by Dr. Behle.

President Kahn—Those who have worked with Dr. Rich since he has been our secretary take great pleasure in expressing our grateful appreciation for the efficient manner in which he has handled the work.

G. F. Roberts—I don't think it ever hurts to commend someone who has done the work that Dr. Rich has done for so many years. I make a motion that the Council be empowered to appropriate a sum for buying some slight memento for Dr. Rich, as a present from the Utah State Medical Association in appreciation of his work.

E. G. Hughes—I second the motion.

A. C. Behle—I think a vote of thanks should be tendered the officers of the university for the help they have given to us for this meeting, and I move that the secretary be instructed to express our thanks and appreciation to them in writing. Seconded by A. A. Kerr, and unanimously carried.

E. P. Mills—I move that we extend our thanks and appreciation to our visitors for their great courtesy in coming here and giving of their time and efforts. That the secretary be instructed to convey this to each of our visitors in writing. Seconded by C. L. Shields, and carried unanimously.

Meeting adjourned *sine die*.

WILLIAM L. RICH, *Secretary*.

When Emotionalism Meets Reason—Louis I. Dublin, Ph.D., told the recent International Birth Control Conference that he disagreed with them. Some of his reasons in brief were:

"Because your propaganda until yesterday has been based essentially on an emotional reaction and not on a scientific analysis."

"Large families among poverty stricken, however deplorable, do not justify a nationwide program of broadcasting contraceptive information without reserve."

"Your effort will simply replace an evil of which we are fully aware and which we all deplore with even greater evils lurking less obviously in the background. There is need for caution; for you are playing with fire. Mistakes in population policy are more easily made than rectified."

"The birth control problem is only one aspect of the larger population question, and will never be settled satisfactorily except as the larger issue is solved."

"I cannot consider the underlying causes for the decline in our birth rate except to point to the very obvious influence of the widespread knowledge of contraceptive methods. One would imagine from your literature that such methods were a recent discovery which, if only applied generally, would release a long-suffering world from all its troubles. But, this is clearly a misconception."

"There is evidence on all sides that birth control practices are in vogue to an enormous degree in the United States. Every doctor, every nurse, every druggist, and every social worker, will, I believe, admit as much. In no other way can we explain the falling birth rate of the country in recent years."

"Knowledge of contraceptive methods is more widely practiced here than in any other country of the world, except Germany and Austria, where the aftermath of the war has taken all desire and incentive for living out of the hearts of the masses. Holland, which you consider the exemplar of voluntary parenthood, shows a birth rate of 26 per 1000, as compared with 23 in the United States."

"You have won much sympathy for your program through the assumption that it works in the direction of social and economic improvement of the poor. But obviously economic battles cannot be fought by other than economic weapons."

"You do not solve the worker's problems by encouraging him to lose his greatest and noblest possession, his children. On the contrary, you help to maintain the status quo by accepting present economic maladjustments without a struggle."

"Have you not a moral obligation to assure those whom you wish to help that the procedures you sponsor are at once effective and harmless? The best medical opinion informs me that you are, in fact, not prepared to make any such guarantees." . . . "Such information as is available indicates clearly that there is still a large element of uncertainty in the suggested procedures."

"You have, heretofore, limited yourselves almost entirely to arousing sympathy for those who have suffered from over-large families. Today, you might very well take up the other side of the picture and help arouse public sentiment in favor of fairly good-sized families among the rank and file of normal people."

"What is most vitally needed today is more light on the problem of population and not wider dissemination of questionable contraceptive practices through such agencies as your current publications."

"Your magazines, sold promiscuously on street corners, are especially offensive and alienate the good-will of many thoughtful people."

CORRESPONDENCE

A DAY WITH ROLLIER

Extracts of a Letter Written by Doctor Langley
Porter to His Associate, Doctor Clain
Gelston of San Francisco

I have just spent a day with Rollier at Leysin, writes Porter. It is the biggest and best-run personal medical enterprise I have ever seen. Thirty-two separate clinic buildings, more than one thousand patients. I thought I had seen some bone tuberculosis, but yesterday I saw four times as many patients suffering with Potts as in all my previous experience—high, low, and dorsal. Three hundred odd additional persons with hip, knee, sacro-iliac, hand, foot, jaw, and cranial tuberculosis—all doing well. Every face smiling except newcomers, all in a good sound state of nutrition and with extraordinary muscular development. The interesting thing is that there is no operating, and no plaster is used. Rollier showed me his abandoned operating and plaster rooms, all the more remarkable, since he began as a surgeon with a predilection for plaster, and now he rejects both because plaster and dressings cut light off the parts and because they cause atonicity and atrophy of muscles.

All repositions are made by posture and traction. Sun and food complete the cure.

Potts cases are kept on the face during the day; on the back at night, with mattress pads to protect the gibbus at first; later pressure pads aid reposition. I did not see a single pressure sore or any unhealthy skin. They use skin friction with alcohol. Knee cases are placed with mattress pad so that the knee is higher than the hip, with the thigh in external rotation; the joint only slightly lower than the knee to limit flexion to a very slight angle. Padded to retain position. Mattresses are of hair. Pads are used of increasing hardness: (1) Coarse millet seed; (2) fine millet seed; (3) sand or hard-packed hair.

The traction apparatuses are simple but effective. Weights over pulleys; very light frames to attach to the bed, easily clamped, easily removed. Two struck me as especially ingenious, one for high cervical and dorsal Potts. All the traction is made from the occiput. A celluloid fitted head piece is fastened to a little carriage running on metal rails. The occiput piece is retained by a band around the forehead, and the pull comes on the sliding carriage, which carries the head up as the weight pulls. It is pictured in Rollier's book. Rollier's finger traction splint also is good. It is an aluminum trough that fits the finger, but runs out to two and one-half times the length of the finger, getting progressively narrower, till at the end the two sides almost approximate and form the bearing for a little pulley (not too little) which carries a traction cord attached to an elastic or metal spring, which in turn is anchored to a wrist piece. It would be fine for sprains and fractures of the fingers, and baseball fingers.

The leg tractions also use the principle of the movable carriage on a light track which is made part of the splint. The management of two non-tubercular patients interested me. In one a spastic paralysis (Little's) traction on the legs in the position of abduction was employed *always at night*, which I think is a good idea.

A system of massage and training is in vogue such as we use, except without hot baths. They have a rather good scheme for training patients in walking. The carriage runs on three wheels, the foreward one hinged for steering. It can be pulled by a nurse while the child follows, or, if the child is able, it can do the steering itself. It might be useful after the child had learned to handle itself after practice on the parallel bar and foot-board combination, such as we use. Besides this, the usual sun treatment is used, and seems to help to gain some relaxation.

The other case was a usual lateral curvature in an adolescent. The whole treatment was day rest on the face, with exercises of the side toward the convexity (1)

by raising the head and shoulders, and (2) by pulling a weight with the hand of that side. The weight is hung quite a bit behind and to the side of the shoulder, and it seems to be working a transformation. Another good stunt is the use of laminaria tents to dilate sinuses that drain poorly. Rollier objects to any cutting that can be avoided. Just slips a small tent into the mouth of the sinus and leaves it twenty-four hours, when drainage becomes free.

As to the use of the sun, we have his principles fairly well in practice. He rarely uses more than three or four hours a day. He begins with small exposed areas with short exposures. Never permits visible reddening of the skin. When there is pain on thickening of the joints, he paints the skin over them with 10 per cent alcoholic solution of eosin, which he thinks permits the better penetration of violet and cuts off red, or vice versa (I shall have to look that up). It might be well to try eosin with the quartz lamp for painful joints, or inflammation in serous membranes. Rollier says that one must take the greatest care with dry peritonitis and with intra-abdominal inflammations, to give only minimal exposures of the tender abdomen to the sun.

I was surprised at the casual attitude toward food. He limits milk to 750 cc; limits meat to two or three meals a week, and uses skinless vegetables, butter, and fruit.

Rollier's clinic is as clean as a pin. I never saw such milky linen or so dustless an institution. He scoffs at those who say lungs cannot be treated by the sun, but, as in peritonitis, minimal exposure to the affected part is essential at first.

Doctor J. A. Simpson, San Francisco, so enjoyed the following editorial clipping from the Paris (Missouri) Mercury that he sends it to us for "our amusement." We pass it on to you:

"The other day a stranger, with the best of intentions, walked into this office and, inquiring for the editor, who is of the elect that suffer from hay-fever, urged him in kindly, though somewhat detached and remote manner, to try Christian Science. At the same time he recommended a St. Louis 'practitioner,' who, for a stated price, could free us of the error that we had a nose and having bereft us of that necessary member, without which a smoke is never a smoke, send us home happy. As a rule, people with hay-fever cures excite the homicidal instinct in us instantly, but something in the man's appearance stayed the hand that would slay. He was small, thin, anemic, wore bi-focal glasses, had on arch-support shoes, and was struggling with a new set of false teeth. His eyes were red and his nose swollen. We thanked him, not altogether ungraciously, and as he stepped out into a beautiful September afternoon filled with millions of golden particles of ragweed pollen floating willy nilly here and there, a paroxysm of sneezing ensued. The human brain is a curious thing. We wonder sometimes how many of the people who prattle about 'science' ever really read 'Science and Health' and 'Key to the Scriptures,' understand the senseless jargon in which they are clothed, or know anything of the personal history of the woman, Mary Baker Eddy, who wrote them. As a child she was a cataleptic, subject to fits of hysteria, in which she fell screaming to the floor, and through the fear inspired ruled the household of her father, Mark Baker, a New England farmer. 'Mary Magdalene had seven devils,' he once declared, 'but our Mary has fourteen.' She gave away her own son when he was seven years old and saw him no more until he was 34. All her life she was an intriguer and trouble-maker, and one by one had to leave the homes that had given her domicile, being even denied shelter by her own sister, Mrs. Tilton. She was illiterate, self-centered, but shrewd. 'Science and Health' was filched almost bodily from Quimby, the Portland clockmaker and faith healer, whose pupil she became after an unsuccessful sortie into spiritualism, and to the end she was a victim of the grossest superstition. Her dominating fear was of 'malicious animal magnetism,' and she even refused to let her mail go through the Boston postoffice, declaring it had been 'poisoned' against her. And yet millions follow this, the greatest meglomaniac of all time, and ascribe to her even the attributes of deity. The brain of the race has cracked."

DOCTOR:

When calling for the active principle of the Posterior portion of the Pituitary substance in solution, remember to specify PITUITARY LIQUID, ARMOUR, because it is made from U. S. government inspected glands and complies with all the requirements of the new U. S. P. X.

There are many Pituitary extracts on the market of varying strength and in order to be sure of your product, we suggest the advisability of insisting on a dependable make and commend to you ARMOUR'S because of the opportunity which our facilities make possible in the selection of raw material.

The same is true of our entire line of glandular preparations. Every particle of raw material put into process is normal in every respect and when insisting upon ARMOUR'S you may be sure of full therapeutic activity.

CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

—milk, produced under the supervision of the New York City Department of Health, whose regulations compel, at each farm, examination of every cow once a year, maintenance of a properly equipped milk house, clean utensils, proper sanitary conditions, and milk maintained under 60 degrees F. until delivered to the Merrell-Soule Plant, where all equipment coming into contact with the milk—most of it glass-lined—is scalded clean daily. Complete laboratory control gives final assurance that nothing but a clean product, free from pathogens, with a low bacteria count shall bear the name KLIM.

*Literature and samples
sent promptly upon request*

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

Effect of Curds on Infant Digestion

One of the most important points about any infant food is its behavior in the stomach.

THE amount of casein in cow's milk is much greater than in human milk, and it coagulates very much earlier in the infant's stomach, forming itself into large, tough masses of curd, while the casein of human milk coagulates much later and sometimes not at all, accounting for the light, flocculent appearance of the curds of human milk, which are quite soft and even in texture.

"Lactogen," by reason of a special method of manufacture, gives a soft, even, flocculent curd almost identical with human milk. Being homogenized, "Lactogen" does away with the danger of intestinal irritation, so frequently met with in feeding the larger butter fat globules of ordinary modified milk mixtures.

"Lactogen" is the new food for infants who are deprived during the early months of infancy of an adequate supply of breast milk.

The coupon below is for your convenience and will bring you sufficient supply for a clinical trial.

Horlick's Malted Milk Co.
RACINE, WIS.

California Association of Medical Social Workers (San Francisco section) met at dinner at "Kentucky Tavern" on Friday, September 18. After dinner the meeting under the presidency of Edna J. Shirsper discussed the subject of "Progress and Changes in Local Medical Social Service Departments."

Eleanor Stockton outlined the reorganization of the San Francisco Health Department, which has gone into effect recently, and introduced as new supervisors Helen Johnston, Supervising Nurse Division of Tuberculosis Nursing; Genevieve Dyer, Supervising Nurse New General Nursing District; Marcella Leonard, Director Social Service, San Francisco Hospital; Eva C. Witter, Supervisor of Foster Homes for Children; Olive McGinnis, Supervisor of School Nurses.

Reba Ingals of the State Board of Control outlined the development in the State Bureau of Children's Aid and the State Department of Public Welfare.

Ida Euler, the new Director of Social Service for the Junior League, told of the plans she had in mind for the development of this agency. Miss Euler is working in close co-operation with the St. Luke's Health Center. The social service activities of the Junior League are principally in the Bernal Heights district.

Bess Raplogel presented a detailed account of the medical social service which is being done by the Red Cross.

Nan Burke has been appointed teacher of hygiene in the Girls' High School. She introduced her successor, Kathleen Kietly, as the new director of social service of St. Mary's Hospital.

N. Florence Cummings discussed staff changes at the Stanford clinics, and told of the practical part of the Stanford course in public health nursing. Dr. Adelaide Brown spoke of Stanford teaching facilities.

President Edna Shirsper presented Aileen G. Crowley, registrar, and Virginia Hayes, visiting nurse, as recent acquisitions to her staff at the Children's Hospital.

"Scotty," who edits the "Personal Punches" column in the San Francisco Chronicle, was a guest and gave an amusing impression of medical social service in his own humorous manner.

Physicians & Surgeons Institute of PHYSIO-THERAPY

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA
THE IMPROVED
ALKALINE WATER

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for effluvia with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water. ASK YOUR PHYSICIAN ABOUT IT.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

The Health Care of the Baby. By Louis Fischer. 15th ed. Review copy by courtesy of the publishers. For sale by advertisers in California and Western Medicine.

This little book is to be highly recommended to mothers, nurses and medical students. It also is a handy book for physicians to consult about the exact preparation and make-up of formulas. It contains many specific instructions, tables, charts, and answers well practically all the questions that trouble the anxious mother.

Newer Methods of Ophthalmic Plastic Surgery. By Edmund B. Spaeth. Review copy by courtesy of the publishers, P. Blakiston's Son & Co. For sale by advertisers in this issue. Price, \$5.

The book is the only one in English as far as we know that is devoted entirely to ophthalmic plastic surgery. In the first chapter are given the details of the general surgical technic and, following this, the various plastic operations are dealt with. The individual cases are clearly described and well illustrated by photographs.

In addition to the author's own carefully and conscientiously set down experiences, the book contains extensive and valuable references to the work of other ophthalmic surgeons.

In an ophthalmic surgery intended "to serve the general ophthalmologist in his every-day practice," we feel more space should have been devoted to the various operative complications and their remedies.

The book is indispensable to those doing plastic surgery about the eye.

The Cerebrospinal Fluid in Clinical Diagnosis. By J. Godwin Greenfield and E. Arnold Carmichael. Review copy courtesy of the publishers, Macmillan & Company. For sale by advertisers in California and Western Medicine.

There are few works on the cerebrospinal fluid, published in English, to which physicians can easily refer.

This book under review is the result of the large personal experience of the authors, who are not only well

trained laboratory investigators, but also experienced neuropathologists.

It always is important to correlate the results found in the laboratory with the findings in clinical practice. The present volume accomplishes this in a lucid manner and concise form, giving the results of the older and the newer tests, such as the hemolysis complement test of Weil and Kafka. The authors found "strong reactions to this latter test were rarely obtained apart from acute meningitis and the syndrome of Froin, and are almost constant in both conditions. Especially when the cerebrospinal fluid contains less than 0.1 per cent of protein, a positive hemolysis test is strong evidence of acute meningitis."

The book is permeated with similar data dealing with deviations from the normal spinal fluid. It is divided into three sections. Part I is devoted to the nature and composition of the cerebrospinal fluid and its changes in disease. It discusses the various methods of obtaining the spinal fluid and the dangers one meets via each route. Part II deals with the spinal fluid in meningitis, syphilis, and other neurological diseases. A very excellent clinical and laboratory differential diagnosis of the various cerebrospinal syndromes concludes this part.

The third and last section is given over to the detail of the technique of cerebrospinal examination.

This feature will be welcomed by all who work with spinal fluids. The techniques for the different examinations are fully described and then discussed with their clinical application. This feature makes for more intelligent co-operation and interpretation.

The volume is replete with valuable information which is easily "get-at-able" and one does not have to wade through scattered pages to collect data on the subject for which he is searching.

An excellent and ample bibliography of the more important publications, arranged according to subject, completes this work.

Pediatrics. Vols. 6 and 7. Edited by Isaac Abt. Review copies by courtesy of the publishers, W. B. Saunders Company.

Volume 6

The sixth volume of Dr. Abt's Pediatrics maintains the standards established by earlier volumes. Volume 6 is of especial interest to all physicians because the major part of it is devoted to the consideration of the infectious diseases of infancy and childhood.

There seems to be some inconsistency in the methods of local treatment of arthritis; the author of this chapter recommends absolute rest and protection for the painful joint, then he advocates rubbing ointment into the same painful joint.

The discussion on diphtheria gives in detail the essen-

(Continued on Page 1498)

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food
Skimmed Milk (1% fat)
Water

8 level tablespoonfuls
9 fluidounces
15 fluidounces

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSÉ, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue
 San Francisco, Calif.

General hospital of 225 beds, accepting all cases except mental diseases. Built upon the pavilion plan, allowing large air space for each patient. The buildings occupy a full city block, built around a beautiful central court. Aseptic, operating and delivery rooms. Complete X-Ray Department with portable apparatus. Eye and Ear, Genito-Urinary Clinics. Modern Hydrotherapeutic Department, etc.

Accredited for Intern training by the American Medical Association.

Alkaline Therapy

IN DISEASED conditions foods (Fats, Carbohydrates, Proteins, Salts and Water) may be oxidized more rapidly than normal.

BECAUSE THE body stores fats, food may be withheld several days with no ill effect.

WHEN NORMAL ALKALIES are withheld, or used faster than supplied, symptoms of ACIDOSIS develop immediately.

NOT A SINGLE cell in the human body can functionate normally if the ACID-ALKALINE

equilibrium has been disturbed.

THERE IS NO therapy or treatment that will restore the patient to health until the normal ALKALINITY has been established.

TO RESTORE the NORMAL ALKALINITY it is necessary to supply the body with a carbonated alkaline drinking water containing the body SALTS AND ALKALIES in the exact proportion for assimilation.

CALSO WATER contains all the body SALTS AND ALKALIES. It is the most efficient and economical method for combating ACIDOSIS. One quart daily is sufficient for ordinary cases of acidosis. Severe cases may require two or more quarts daily.

CALSO WATER is indicated in the acidosis of: Diabetes; nephritis; toxæmias of pregnancy; cyclic vomiting of children; infections; cystitis; urethritis; headaches of high blood pressure; gastric hyperacidity; bronchial asthma; urticaria. In the preparation and post-operative treatment of surgical patients.

Calcium Deficiency

NOT ALONE for the creosote content may CALCREOSE be administered but also for its calcium content. Many physicians are prescribing calcium to overcome a calcium deficiency.

CALCREOSE is a mixture of approximately equal parts of creosote and calcium oxid that can be taken for a long time, and in comparatively large doses without apparently causing any gastro-intestinal disturbance; nor do patients object to its long continued use.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

Little Basin Ranch as a New Health Resort

The Little Basin Ranch, in the heart of the Santa Cruz Mountains, often spoken of as "Little Yosemite," and one of the most beautiful places in California, may be converted into a health resort, if plans already under way are carried out.

The ranch is within easy access of San Francisco and the Bay Region, and because of its ideal climate, it has been decided to establish a sanitarium, in the Little Basin itself, which will combine the features of a beautiful summer resort with that of a health resort.

The Little Basin Ranch consists of six hundred acres of wild mountain and valley, much of which is timbered and through which a beautiful mountain stream finds its way, supplied by numerous springs, located on the ranch. Ten acres of the valley bottom are under cultivation, planted to grapes, walnuts, and a variety of fruits and berries, while a portion of the ranch is stocked with thoroughbred Angora goats.

With this wonderful supply of mountain spring water, the fine elevation and scenery, there is no spot on the Pacific Coast more ideal for the development of a project such as the proposed resort.

Those interested in a project of this nature may secure information by addressing CALIFORNIA AND WESTERN MEDICINE, Box No. 950.

BOOK REVIEWS

(Continued from Page 1492)

tials in diagnosing, treating, and preventing diphtheria, which includes the technic of the Schick test and the administering of toxin-antitoxin.

The chapter on scarlet fever places at our disposal the recent work done on scarlet fever, the most important being that of the Dick's, in which they have developed the test by which individual immunity and susceptibility may be determined. The methods are presented in sufficient detail.

This volume embodies many recent important advances made in scientific research, as well as the results of long experience on the part of the various authors who have contributed to the book.

Volume 7

This seventh volume is devoted to the nervous system of childhood. It maintains the high standard found in the previous volumes, and leaves little room for criticism.

The infantile cerebral palsies are well covered, but it appears that too much stress is laid on syphilis as an etiologic factor, while the role played by the prolonged coagulation time of the blood in certain newborns is apparently overlooked.

"Surgery of the Head and Spine" is well written, complete, and contains numerous pertinent illustrations. The present-day knowledge of chorea is condensed and incorporated in a well-prepared chapter.

Acute poliomyelitis is elaborately considered from all angles, but it is unfortunate that the therapeutics are not given in more detail.

The volume is rounded out by interesting chapters on the psychopathology of childhood, defects of speech, and one on the sexual life of the child.

Smallpox Influences History—India is one of the greatest present sufferers from this scourge. In the years 1918 to 1922 nearly 650,000 deaths from smallpox were reported. China pays a huge annual toll in sickness, damaged bodies, and lives to this account. Scotland, Germany, France, Spain, Australia, Burma, Mexico, Brazil, Argentina, Chile, Costa Rica, Santo Domingo, and Canada have all had epidemic visitations within the last five years. Once more the disease has assumed epidemic proportions in England, where the false prophets of anti-vaccination still preach their dangerous doctrines that smallpox has become a trivial disease, that it can be controlled by sanitary measures alone, and that vaccination is impotent to protect against infection.

Interior view showing the completely equipped hospital-operated laundry of St. Mary's of the Palms Mission, San Jose, Calif.

View from yard of St. Mary's of the Palms Mission, San Jose, Calif.

Fresh, Clean Linens . . . all the time... at St. Mary's of the Palms Mission

THINK of the satisfaction of having an almost unlimited supply of freshly laundered linens on hand ready for immediate use!

Ever since the installation of a laundry within its own walls, St. Mary's of the Palms Mission, San Jose, Calif., has been enjoying that satisfaction. Now, just as fast as table and bed linens, curtains, towels, and wearing apparel are soiled, they are laundered sweet and clean, and returned to service. There is always a supply on hand, ready to be used.

Besides this advantage, officials at St. Mary's can maintain a closer supervision of their

laundry work. And they are able to keep a smaller amount of linens in stock because of the rapidity with which they can be cleansed and made ready for service again. The convenience and speed of the hospital-operated laundry certainly justifies its installation.

Hundreds of hospitals, schools, and other institutions over the country now have their own laundries. A corps of engineers is maintained by The American Laundry Machinery Company to furnish plans and specifications or to advise with any institution that is considering the operation of its own laundry. A postal card will bring full details—without obligation.

Therapy*

FOR LOCAL INFLAMMATORY PROCESSES

The SOLLUX LAMP, equipped with conical reflector, provides an excellent means for the local application of luminous heat rays in the alleviation of pain caused by inflammations. Beneficial results have been noted particularly in the treatment of Hematomata, Ankylosis, Tendosynovitis, Periostitis as

well as in glandular troubles, Orchitis, Epididymitis and Prostatitis.

Used without the least inconvenience, the SOLLUX LAMP produces a powerful hyperaemia which penetrates very far and lasts a long time. By use of the parabolic instead of the conical reflector, general body radiation, or combined radiation in conjunction with the Alpine Sun Lamp, may be had.

The SOLLUX LAMP is marked by wide flexibility, simplicity in operation, great cleanliness and economy of current consumption. And, its pleasing appearance makes it an ornament for any consulting room.

STATE

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (Inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

The Relationship of Tuberculosis to Fistula in Ano—It is the belief of W. A. Fansler, Minneapolis (Journal A. M. A.), that we are not justified in making the diagnosis of tuberculous fistula except by definite microscope picture or in cases in which the lesion has the typical appearance described elsewhere in this paper. Considering all cases of fistula in ano, it is doubtful whether more than 2 or 3 per cent are tuberculous in character. Tuberculosis is very rarely primary in fistula in ano. If it occurs at all it is not more than a small fraction of 1 per cent. Probably 15 per cent of fistulas occurring in tuberculous patients are tuberculous; 0.33 per cent of tuberculous patients also have tuberculous fistulas. (These figures are based on a too insignificant number of cases to justify a positive statement.) In view of the ease with which the tubercle bacillus affects the mucous membrane of the bowel, it would seem possible that in some cases—at least in tuberculous persons, in whom the fistulas appear to be a simple inflammatory process—that the original lesion in the bowel wall is due to the tubercle bacillus. However, this is purely a matter of opinion and has not been proved. In any event, it has but little bearing on the prognosis or treatment of the fistula. It is probable that tuberculosis as such has a tendency toward the formation of rectal fistula, but that this tendency is not as great as is generally supposed. The general condition of the patient is also a decided factor. It would seem that the formation of rectal fistulas in persons who are underweight is undoubtedly a definite warning of the presence of pulmonary tuberculosis or of a tendency toward its development. These persons are entitled to a most scrutinizing general examination, which, even if negative, should be repeated periodically.

Please, doctor, be warned of the danger of prescribing for drug addicts and alleged addicts. The fact that one of them may be an under-cover agent is the least important of the problems of such a practice.

Wantz Multiple Wave Generator for Sinusoidal and Galvanic Therapy

"Of all human ambitions an open mind eagerly expectant of new discoveries and ready to remold convictions in the light of added knowledge and dispelled ignorances and misapprehensions, is the noblest and the most difficult to achieve."

—James Harvey Robinson in "The Humanizing of Knowledge"

A Point of View

The Victor X-Ray Corporation owes its leadership in the manufacture of X-ray and physiotherapeutic apparatus to a point of view.

This point of view recognizes the fact that roentgenology and physiotherapeutics are ever evolving new methods which must be reckoned with both by the physician and by the manufacturer of medical apparatus. But what new methods are sufficiently advanced for acceptance in practice the medical profession alone is competent to decide.

Hence, while the Victor X-Ray Corporation keeps abreast of the progress made by medical research it introduces only such apparatus as open-minded physicians are convinced they need.

Thus both medical progress and medical conservatism dictate the character of the roentgenological and physiotherapeutic apparatus developed by the Victor X-Ray Corporation.

Let us advise with you in the selection of X-ray equipment that best meets your individual requirements. If there is some phase of physiotherapy on which you would like authoritative reprinted articles, we have them. You don't obligate yourself to buy when writing us for suggestions or literature. Use the coupon below.

PLANTS WHICH CAUSE HAYFEVER

UNDER the above title a new monograph—amply illustrated—has just been released from the press. The urge to prepare the booklet came directly from the physician himself who submitted first one question and then another and wrote from this or that section of the country and at all seasons. Therefore, in attempting to prepare a collective answer or rather a collection of answers, we were obliged to consider the sectional as well as the seasonal requirements throughout the land.

Copies Now Available on Request

THE ARLINGTON CHEMICAL COMPANY
Yonkers, New York

DENNOS

for gruel

Especially desirable because it contains the mineral salts of whole wheat.

A comparative analysis shows (1 ounce)—

	Barley Flour	DENNOS
Protein195	.37
Carb.	2.093	5.090

One level tablespoonful of DENNOS yields approximately 58 calories.

Send for booklet, "Artificial Infant Feeding" which outlines a simple, practical method, based on the actual metabolic requirements of the infant.

Samples and literature sent on request

To Our Customers

We maintain fully equipped commercial and research laboratories with facilities for all classes of analytical determinations. These additions to our plants have made it possible to conduct routine quantitative tests on all of our products, thus insuring you against fatalities due to hap-hazard production.

In addition to medical gases we also manufacture a full line of intravenous and intramuscular medications and are prepared to make up special formulas.

We solicit your co-operation in the ethical advancement of intravenous medications as well as anesthesia.

Sutter Hospital

Corner Twenty-eighth and L
Sacramento, Calif.

BOARD OF DIRECTORS

GEORGE A. SPENCER, M. D., *President*

GEO. A. BRIGGS, M. D., *Secretary*

E. T. RULISON, M. D., *Treasurer*

F. N. SCATENA, M. D.

W. A. BEATTIE, M. D.

ELLARD L. SLACK, *Superintendent*

The location of the Sutter Hospital is particularly advantageous. It is very accessible, due to a number of car lines serving it. Plenty of parking space is also available. Its outstanding feature, however, is its quiet location, overlooking Sutter's Fort and its beautiful grounds.

It is a thoroughly fireproof, general hospital of 174 beds, a complete children's department and an entire floor devoted to maternity work.

It is a new hospital completely equipped with the best and most modern equipment—including an X-ray laboratory with deep therapy unit.

Kitchens and diet laboratory are under the supervision of graduate dietitians.

The Sutter Hospital is owned by a corporation and operated by a Board of Directors—through a chief officer and staff.

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Laboratory Products Co.—Protein S. M. A. (Acidulated).

Eli Lilly & Co.—Antistreptococcic Serum, Normal Horse Serum, Pertussis Vaccine, Pneumococcus Vaccine Prophylactic, Staphylococcus Aureus Vaccine, Staphylococcus Vaccine, Streptococcus Vaccine, Vaccine Virus.

Merrell-Soule Co.—Vi-Mal-Dex (Orange).

Parke, Davis & Co.—Corpora Lutea Desiccated (P. D. & Co.). Capsules Corpora Lutea Desiccated (P. D. & Co.), 2 grains; 5 grains. Tablets Corpora Lutea Desiccated (P. D. & Co.), 2 grains; 5 grains.

Insulin—Squibb 10 Units, 10 Cc.—Each cc. contains 10 units of insulin—Squibb (New and Non-official Remedies, 1925, p. 174). E. R. Squibb & Sons, New York. Also 20 units, 40 units, 80 units.

Neo-Silvol Ointment, 5 Per Cent—An ointment composed of Neo-Silvol (New and Non-official Remedies, 1925, p. 379), 5 per cent. in a base composed of glycerin, benzoinated lard, hydrous wool fat and petrolatum. Parke, Davis & Co., Detroit.

Mercurosal Solution—Each cc. contains mercurosal (New and Non-official Remedies, 1925, p. 234), 0.025 gm. (5/13 grain), in distilled water containing 0.1 per cent of sodium citrate. Parke, Davis & Co., Detroit.

Theocalcin—A double salt or mixture of calcium theobromine and calcium salicylate. It contains not less than 44 per cent of theobromine. Theocalcin acts like theobromine, but is claimed to be less likely to produce gastric irritation than the official theobromine sodio-salicy-

late. It is supplied in bulk and in 7½ grain tablets. E. Bilhuber, New York.

Vi-Mal-Dex (Orange)—A mixture containing approximately, maltose, 28 per cent; dextrose, 10 per cent; dextrin, 48 per cent; orange juice sugars, 9 per cent; citric acid, 1 per cent; ash, 1 per cent; moisture, 3 per cent. One hundred gm. contains the equivalent of 93.5 cc. of fresh orange juice. Vi-Mal-Dex (Orange) is proposed as a carbohydrate food for use in the feeding of infants. In addition to the carbohydrates, dextrose, maltose and dextrin, it presents the anti-scorbutic properties of orange juice. For use, Vi-Mal-Dex (Orange) is mixed with water or milk. Merrell-Soule Co., Syracuse, New York.

Doctors are Taken En Masse—Let a doctor err, once or many times, and forthwith behold the condemnation of the entire profession. Yet while the failings or foibles of a divine may be ridiculed or condemned, critics never dream of charging his creed with the faults of the man. Let a lawyer lie or a judge be bribed, or a witness perjured, yet the majesty of the law is not impugned.—Editorial, Illinois Medical Journal, September.

Hospital and Surgical Supplies — Wholesale and Retail

Low in cost—big in scope —compact in size

The Rieber X-Ray Unit costs less than any other device of comparable efficiency ever sold. The price is \$1500.00 F. O. B. San Francisco. Easy terms of payment can be arranged if desired.

This extremely low price gives you the very highest type of construction, and is made possible because the various units which go to make up an X-Ray machine are combined in one single, compact, practical device.

The Rieber X-Ray Unit gives you both fluoroscopy and radiography. Its controls are centralized and always easily in reach of the left hand and foot from the front.

Fluoroscopic screen has 30-inch vertical and 12-inch horizontal movement. For radiography, special switch is provided which gives high milliamperage for short exposures.

Instantly detachable cassette holder takes all standard films and moves with carriage in all directions. It is always at a fixed distance from the tube insuring unfailing focus.

A room or corner of the office four feet wide by eight feet long houses the Rieber X-Ray Unit. Weight is 650 pounds.

We have a very attractive brochure which shows and describes the Rieber X-Ray Unit in detail. We will gladly mail it to you without cost or obligation. Just send the coupon below.

MINERAL WATERS

"Mineral waters possess no mysterious or occult virtues in the treatment of disease. No mineral water will be accepted by the medical profession for alleged medicinal properties supported only by testimonials from bucolic statesmen and romantic old ladies."

Prepared and Issued by the
PROPAGANDA DEPARTMENT
of the Journal of the American Medical Association
535 North Dearborn Street, Chicago

1923

2130

The above is a fac-simile of a pamphlet published by the A. M. A., containing important information regarding mineral waters; a copy should be in every physician's library. Upon request a copy will be sent, postpaid, to any physician. Address Bureau of Hygiene and Research, Box 10, Arcade Station, Los Angeles.

This page is published upon the authorization of the

BUREAU OF HYGIENE AND RESEARCH, PURITAS WATER DIVISION,
LOS ANGELES ICE AND COLD STORAGE COMPANY, LOS ANGELES.

Largest manufacturers and distributors of Distilled Water in the world.

* Little Stories About Living Trusts

"My practice suffers"
—said the doctor.

"All in all, looking after my business affairs interferes with proper attention to my practice--it costs me money and is robbing my patients of time I should be devoting to them."

After poring over his investment ledger one morning, Dr. S—— had come to a Trust Company for advice as to how he might rid himself of some of the bothersome details attaching to his financial affairs, and insure for those affairs safe, economical management.

How he learned about the Safekeeping Account, its efficiency and flexibility, its remarkably low cost, is told in our new pamphlet—"There Aren't Enough Hours in the Day".

P. O. Box 507, Santa Barbara, California

The Non-Surgical Management of Peptic Ulcer by the "Physiologic Rest" Method—The material analyzed by Frank Smithies, Chicago (Journal A. M. A.), comprises 470 patients affected with ulcers and who were treated non-surgically according to Smithies' plan published in 1916. In the hospital cases, the average duration of incarceration was twenty-six days, a saving of nearly half the time and money required by the regimen advocated by Ewald, Schultz, Sippy, and others. Actual bed confinement averaged less than nine days. In 40 per cent of patients, all pain had disappeared within twenty-four hours of beginning treatment; an added 33 per cent experienced pain relief within forty-eight hours; 8 per cent required seventy-two hours; 15 per cent almost ninety-six hours; in approximately 4 per cent it was necessary to relieve pain by opiates. The last group consisted of ulcers whose extension had advanced to the serous layer of the stomach, or the ulcers were of the deep, fissured type, directly located at the pyloric or cardiac orifice. A total of 81 per cent were subjectively comfortable in three days or less. Of 41 per cent of ulcers exhibiting positive occult blood tests when treatment was begun, at the end of five days 92 per cent of the patients' stools were blood-free. Seven cases went on to actual perforation (1.5 per cent). In sixty-six patients who came to laparotomy for numerous intra-abdominal lesions, following institution of ulcer management, completely healed scars were demonstrated in fifty-four, approximately 82 per cent. In the remaining twelve patients, malignancy, perforation, multiple ulceration or actual benign ulcer activity were present. Dyspepsia-free intervals averaging eleven months were recorded in 234 cases before treatment; it lengthened to thirty-seven months as an average after treatment. Thirty-two patients before treatment had had quiescent periods averaging nineteen months; after treatment those on whom we have reports had increased to an average of forty-four months. Recurrences were noted in 14 per cent (sixty-six cases). Of the whole group, 470 patients in their present status, there is justification for claiming cessation of the ulcer process in 361, or 77 per cent.

SANTA BARBARA COTTAGE HOSPITAL

"A Splendid Hospital in an Ideal Location"

Location—Santa Barbara, California, where ocean and mountains meet. Climatic conditions are perfect.

Metabolic Department—Diabetes and Metabolic Diseases are made a specialty.

Roentgen and Radium Department—Complete equipment for treating any malignant or non-malignant condition.

Cardiac Department—The equipment of this department, as well as the location of the hospital, makes conditions excellent for patients suffering from cardiac disturbances.

School of Nursing—The diversity of the work done by the hospital offers exceptional inducements to the prospective student. The Louise Savage Knapp Hall for Nurses, where the students live, is not surpassed in California.

Adapted to Breast Milk

The Anti-Rachitic Property of S. M. A.

EARLY in the experimental work on S. M. A., cod-liver oil was recognized in its important double role as a source of fat soluble "A" growth factor, and as a preventive and cure of rickets. *Ever since 1914*, there has been incorporated into the fat of S. M. A., an adequate amount of cod-liver oil. From the very beginning, too, only the highest quality of cod-liver oil has been used.

Thousands of physicians are prescribing S. M. A. with excellent results. They are assured that the infant automatically has an adequate amount of cod-liver oil to prevent rickets and spasmophilia. They recognize this anti-rachitic property as only *one* of the *many* sound nutritional principles embodied in S. M. A. Samples and literature sent upon request.

S. M. A. is manufactured by

Feeding Babies in Winter

Neither cow's milk nor breast-milk contains sufficient antirachitic power to protect all infants from RICKETS.

Also—during the winter months, babies are usually not exposed to a sufficient amount of sunlight to prevent RICKETS.

The prescribing of MEAD'S STANDARDIZED AND BIOLOGICALLY-ASSAYED COD LIVER OIL by the physician is one of the most valuable safeguards against RICKETS.

MEAD'S is not an ordinary COD LIVER OIL. Every step in its preparation, from the time the fish are caught until the oil is finally tested and bottled, is scientifically controlled. Its purity and potency is guaranteed.

*Samples and literature furnished
immediately on request.*

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

"Advertising," says Mr. Francis H. Sisson, Vice-President of the Guaranty Trust Co., New York, "is on the threshold of its golden age. Its possibilities for service challenges the most far-reaching imagination. That day is long past, if indeed it ever existed, when advertising under proper conditions, can be considered as an experiment or a speculation. Advertising has long since become a demonstrated factor as a business builder and a clearly proved educational force. That advertising may not always, in all hands, operate 100 per cent efficiency, is no more proof of its failure than an unsuccessful operation on the human body by a horse doctor would be a proof of a failure of surgery."

While we physicians criticize the people for the readiness with which they accept the theories and teaching of unscientific healers, we are ourselves ready to accept the carelessly reported results of some new method of treatment.—Editorial, Journal Kansas Medical Society.

Testimonials, according to Morris Fishbein (Medical Follies), can be bought in wads of five thousand from a Manhattan firm. As an example:

"Dear Doctor—Before taking Chiropractic and Electric Treatments, I was so nervous that nobody could sleep with me. After taking six treatments anybody can sleep with me."

Niles Home for Aged

Niles, Alameda County, Calif.

PHONE 106

Forty minutes from Oakland. Two railroads, Oakland and San Jose stages. New fireproof building—one floor and no steps. Beautiful grounds, shade and fruit trees. Excellent climate. Reasonable monthly rates. Graduate nurse.

DR. GOTTBRAITH'S

Belmont, California

A select private home for the treatment and care of nervous patients, conditions of semi-invalidism and aged people. All patients are under our immediate and personal care and are shown every attention and courtesy. Number of patients limited.

for Non-Sugar Diets

Famous S&W quality canned fruits, packed in *sterile water or natural juice*, instead of syrup.

Nutradiet canned fruits contain a minimum of carbohydrates. They contain less sugar than the fresh fruit itself because a portion of the natural sugar is thrown off into the water.

May be prescribed in cases calling for non-sugar diets. Write for chemical analysis of Nutradiet fruits. Also list of grocers having them for sale.

[Nutradiet salt-free vegetables include a variety of vegetables packed without salt or sugar.]

GLAND PRODUCTS

Specification the Surest Guaranty of Clinical Results

UNIFORM methods cannot be employed for the extraction and desiccation of different glands. The best method of handling each gland must be determined by experiment, the processes of manufacture in each instance being designed with reference to the peculiarities of the particular gland in question to yield a satisfactory finished preparation.

The identity of the gland is of first importance, and this is particularly true of parathyroids. It is very easy to confuse other glands with the true parathyroid glands.

All glands employed by us must be normal. They are all examined for evidence of disease. Before desiccation, all non-glandular matter is removed; this procedure reduces the weight of the glands as they reach us, often to a large extent.

The greatest care is also exercised to select and dissect only that part of the gland which is required in the manufacture of the product, such as the corpus luteum, from ovaries, the anterior lobe from the pituitary body, ovarian residue from ovaries and the posterior lobe of the pituitary. Some glands, such as the thyroid, thymus, pineal, etc., are utilized in entirety. Where fatty tissue is present in excessive quantity it is removed by solvents in a way to prevent injury to the active gland substance.

To still further increase the activity of our gland products we pass the desiccated material, after it has been finely powdered, through sieves to get rid of the remnants of inactive fibrous and connective tissue.

Our gland products therefore represent only the useful parts of the raw material we receive, and for this among other reasons contain a maximum amount of the therapeutically active portion of the glands.

Only by specifying our gland products—by adding to his prescription for gland products the designation "P. D. & Co.," can the benefits of the careful work we do be secured by the prescriber.

We will gladly send literature on the gland products in which you are interested.

Lilly's Scarlet Fever Antitoxin

The United States Public Health Service issued to Eli Lilly and Company the first license to manufacture Scarlet Fever Streptococcus Antitoxin.

Lilly's Antitoxin is made by the Dochez method, which makes it possible to obtain an antitoxin many times stronger than the official requirements. Its great potency permits a dose of very small volume.

Each lot of Lilly's Antitoxin is tested by a control lot which has been proved therapeutically.

Lilly's Antitoxin is offered only in the concentrated form: A-80, Prophylactic Package; A-82, Therapeutic Package. Write for further information.

TRAINING THE PATIENT

**DESHELL
AGAR FLAKES
(American)**

So much interest has been created in the superior American made Agar used in PETROL-AGAR (Deshell), that we have decided to place it on the market as DESHELL AGAR FLAKES, (American), for the physician who, in certain cases, may wish to prescribe agar.

DESHELL AGAR FLAKES (American) are produced in a modern American factory on the California coast.

They are free from impurities, sterilized, free from starch—which affords at least 25 per cent additional bulk.

DESHELL AGAR FLAKES (American) are unusually palatable.

They can be obtained on prescription from any pharmacy.

The successful treatment of constipation is largely dependent on proper education of the patient.

PETROLAGAR (Deshell), in a vast majority of cases, automatically relieves the condition, because of the natural protective functions of the body in resuming normal conditions when a soft, easily passed stool reinstates the natural movement.

In the exceptional or difficult case, however, an understanding of other facts is involved. Addiction to cathartics, loss of tonicity, the necessity of adhering to a definite "Habit Time," and the necessity for keeping the rectum empty when it should be empty—call for much more dependence on the instigation of proper habits than on any remedy.

The physician, therefore, should educate the patient to educate himself to a proper "Habit Time," should insist on the proper diet and exercise.

PETROLAGAR (Deshell) is an aid which greatly shortens the period of education. When the "Habit Time" is established, PETROLAGAR (Deshell) should be discontinued, but the definite habit should be insisted upon because a lapse from this is likely to bring a return of the constipation.

PETROLAGAR (Deshell) has been accepted for *New and Nonofficial Remedies* by the Council on Pharmacy and Chemistry of the American Medical Association.

PETROLAGAR (Deshell) is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

A ONE-DRUG Cough Remedy

IN contrast with the "shot gun" cough remedies, **THIOLCOL SYRUP "ROCHE"** contains *only one drug*, thiocol.

No narcotic, not a single cough deterrent, not another active cough combatant is in it—THIOLCOL *alone* is sufficient. A pronounced and effective sedative expectorant which exerts a beneficial effect on the respiratory tract, and definitely aids in subduing the cough.

"Thiocol is comparatively tasteless, does not disturb digestion, and is non-toxic." (*New and Nonofficial Remedies of the A. M. A.*, 1925, p. 101).

These advantages, and the absence of any cloying sweetness, stamp **THIOLCOL SYRUP "ROCHE"** as a distinctive remedy—and one which can be given with safety to the youngest children.

MARY'S HELP HOSPITAL

145 Guerrero Street, San Francisco

Accredited for Intern Training by the American Medical Association.

Accredited School of Nursing.
Open to All Members of the California Medical Association.

Institutional Member League for the Conservation of Public Health.

A limited general hospital of 150 beds, owned by the Archdiocese of San Francisco, and operated by the Sisters of Charity. All classes of patients are admitted except those suffering from communicable or mental diseases. The hospital was organized and incorporated in 1892. All buildings were destroyed by the fire in 1906. A complete new modern hospital was finished July 2, 1912. Mary's Help Hospital is well located, well constructed, well arranged, and well equipped for good service.

Troy Laundry Machinery Co.,
East Moline,
Ill.

Gentlemen:

You perhaps will be pleased to know that the 30" x 42" Service Drying Tumbler, Belted Motor Drive, which we purchased thru your representative Mr. Gleason sometime ago has been a treasure. We have been forced to crowd it to its utmost capacity but to date we have not had the slightest trouble with it.

We believed when we made our choice that it was a wise one, but we can truthfully say today that we were wiser than we thought.

We sincerely thank Troy Laundry Machinery Company and Mr. Gleason in particular for persuading us to make this efficient purchase.

Sincerely yours,

THE CHILDREN'S HOSPITAL

Arthur O. Bauss
Gen'l Superintendent.

AOB:MD

For the small hospital laundry no better drying tumbler is built than the Troy Service Dryroom Tumbler. The above letter from Mr. A. O. Bauss is convincing proof that the machine "delivers the goods" and that Troy service and equipment is a wise choice.

Troy laundry machinery has proved equally satisfactory in many other representative hospitals and institutions. A staff of Troy experts is always ready to advise you concerning any laundry problems which you may have. This service is offered without any obligation.

Quack Advertisements Denounced—The Executive Committee of the Association of National Advertisers, which is composed of representatives of concerns whose combined advertising budgets exceed \$150,000,000, has recently adopted resolutions calling on the members of the association to discourage the advertising of medical preparations offered as preventives of, or cures for, such diseases as tuberculosis, and cancer, which are at present regarded by the best minds of the medical profession as incurable so far as treatment with drugs is concerned . . . to spread misinformation on such a vital subject is . . . to commit a social crime.

The committee calls attention to the fact that every advertisement that perpetrates a fraud or causes a sneer from intelligent readers increases the reputable advertiser's task and his selling cost.

The National Vigilance Committee, which publishes the Truth-In-Advertising Bulletin, in commenting on these resolutions says:

This type of advertising must go. It costs all of us too

much—cost in human life, in taxes paid for the support of indigent victims, in direct damage to the business of every enterprise which employs advertising to create markets and sustain good-will.

This is distinctly encouraging. The patent medicine manufacturer depends on advertising. If the members of the National Advertisers' Association heed the recommendations of their Executive Committee, a long step will have been taken toward the suppression of this pernicious business.—Health News.

Speaking to or writing for non-medical audiences "is much more difficult than it might seem," says Morris Fishbein (Maine Medical Journal), "because a physician who can write an excellent scientific paper, who can tell you the most intimate details of the removal of an appendix or a gall-bladder, or who can tell you just how the bacteria get out of an infected tonsil and cause an ulcer of the stomach, speaks an unintelligible language when he tries to tell these things to the average layman."

The Dietetic Value of Gelatine

Receives High Recognition

The edition (6th) of "Diet in Health and Disease" by Dr. Julius Friedenwald and Dr. John Ruhräh, published by W. B. Saunders Company, Philadelphia, contains the following tribute to the value of Gelatine in feeding infants and children:

JACOBI in 1879 suggested the use of Gelatine in infant feeding, and it has been used some ever since, but only recently has the real value of Gelatine in the diet been made more widely known. It is very useful in rendering milk mixtures more digestible, preventing both gastric and intestinal indigestion by preventing the large, hard curds. Where the appetite is poor, the addition of Gelatine makes the milk more palatable for some children. It is of value in infants who regurgitate or vomit their food, in diarrhea particularly where there is putrefaction. It is useful where gas is formed, either in the stomach or the intestines, and in fermentative conditions in general. It is useful in preventing colic in some babies, and in the breast fed may be given in solution just before feeding. In infants who are constipated and who have large, hard stools which do not adhere to the napkin, the addition of Gelatine to the formula usually corrects the difficulty. It is of great value in celiac disease, not only in supplying additional much needed food, but in correcting the accompanying indigestion. In malnutrition the addition of Gelatine to the dietary is of great value, as it is in those who have lost weight through operations, fevers, or other illnesses. It has also been suggested in scurvy."

Knox Sparkling Gelatine—highest quality for health—is the purest form of plain granulated Gelatine, produced by the most scientific methods, and under constant bacteriological and chemical laboratory control. It contains no artificial flavoring—no sweetening.

In prescribing Gelatine for the diet, physicians should be extremely careful to specify *Knox Sparkling Gelatine*.

FREE—TO PHYSICIANS AND HOSPITALS

The physician's reference book of nutritional diets with recipes will be sent free to physicians or hospitals, upon request, if they will address the Knox Gelatine Laboratories, 417 Knox Ave., Johnstown, N. Y.

In addition to the family size packages of "Plain Sparkling" and "Sparkling Acidulated" (which latter contains a special envelope of lemon flavoring), Knox Sparkling Gelatine is put up in 1 and 5 pound cartons for special hospital use.

*Radium
and
X-Ray Therapy*

Radium and Oncologic Institute

1052 West Sixth Street, Los Angeles

This institution provides unexcelled equipment and facilities for the use of Radium, X-ray and Allied Agents in the treatment of neoplastic and other appropriate diseases.

Radium Therapy—An adequate quantity of radium and complete emanation apparatus and appliances afford the facilities essential for modern technique in radium therapy.

Deep X-ray Therapy—Two complete 300,000-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

Hospital Affiliations with several institutions, including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

Radium Service—Radium applicators may be secured after consultation by the physician when advisable for his use in appropriate cases.

*We desire to confer and cooperate
with the medical profession, and wel-
come inquiries pertaining to this work*

REX DUNCAN, M. D.

E. D. WARD, M. D.

1052 WEST 6th STREET

LOS ANGELES, CALIFORNIA

I venture to predict that in the future all intelligent men and women will have their own health physician to whom they will look to keep them well and vigorous. This will not come until the public recognizes the fact that the physician can adequately give this service. To hasten the day and to insure its coming, we shall be wise to address ourselves to the task of becoming as efficient and successful in this field as in the field of prevention of communicable illness and the cure of disease. I propose the name of health client for the candidate for the health examination, dispensing with the customary term "patient." The health client comes to the physician not to be relieved of a pain, but to be fore-guarded against it. He is impelled by wisdom, counselled by caution. He wishes to live long and keep well. The scope of the health examination is extensive. It covers the whole man—his past and present, and seeks to recast his future in a larger mold. The usual examination is intensive, seeking a clear definition of the pathological condition. The health examination, therefore, consumes more time, requires a broader vision, and a wider and greater scope. The health examination has four fields: 1. Heredity and collaterals. 2. Habits and hazards of life. 3. Diseases—past, present, and future. 4. Prescription and instruction of client. The health examination is not a perfunctory fifteen-minute survey, ending with the assurance that "You are all right. I would recommend you for any amount of insurance." It is an important event in the life of the client, and *not less than an hour's hard, well-directed work on the part of the physician is required*—C. Ward Crampton (Medical Journal and Record).

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

No. 12

THE STATUS OF THE CLINICAL PATHOLOGIST

By ROBERT A. KILDUFFE, M. D., *Director Laboratories Atlantic City Hospital,
Atlantic City, New Jersey (formerly of Los Angeles)*

IN EFFECT, Doctor Kilduffe's article and the many and interesting discussions constitute a symposium on one of the much-discussed angles of medicine and health progress.

It is often necessary for an editor who examines hundreds of manuscripts a year to drive himself through some of his work. Then, again, copy comes along that is so intensely interesting that the editor lays his "blue pencil" aside and gives himself up to the joy of reading. This symposium is in the latter class. Rarely will the physician reader encounter so many clearly elucidated angles to a vexing problem as are here brought together—by men who do not, by any means, entirely agree.—Editor.

Discussants are M. C. Terry, John W. Shuman, Elmer W. Smith, E. H. Ruediger, William F. Cheney, Wilfred H. Kellogg, William Ophuls, L. S. Schmitt, Newton Evans, Rene Bine, A. W. Hewlett, William J. Kerr, Stanley Stillman, Gertrude Moore, F. R. Nuzum, Walter V. Brem, A. M. Moody.

tion, but it is surprising and not so readily explained to find a source of information and authority standing sponsor for the dictum that "the status of the clinical pathologist is not the same as that of the internist or surgeon. The latter deals with variables—human beings—the former conducts manipulations on fixtures—inanimate substances."

Fortunate it is, indeed, that even a pronunciamento of authority may—when needs must—be subjected to scrutiny. Unfortunate it is, also, that by many this statement will be accepted at its face value as crystallizing a somewhat common idea that the clinical pathologist, in some ways, stands apart from other men and that, in some way yet to be exactly defined, his qualifications are different from and, perhaps, less exalted than those of his purely clinical brethren.

That some such attitude exists cannot be denied; that it can be justified may be disputed. The responsibility for its inception can only be placed with difficulty—if at all; for its continuance the clinical pathologist himself is largely responsible.

In the early days of medicine it was comparatively easy to separate the medical profession into three broad groups:

I. Those, comparable to the physician of today, who studied the patient and his symptoms and proceeded accordingly and whose work was done within the living body of the patient, as it were.

II. Those, comparable to the surgeon, whose work was done *on* the living body of the patient; who rearranged it and improved upon the defects of nature and who, as many have maintained, detected and corrected the errors of the first group.

III. Those, pathologists as originally conceived, whose work was done largely independently of the living body in a study of the causes and effects of disease and its mechanism and who, inadvertently, at times revealed the errors of omission and commission of both the preceding groups.

In those comparatively prehistoric days the field of laboratory examination was restricted, the tests

ANYONE attempting a classification of physicians as individuals or groups, in accordance with their qualifications or attainments, is apt to find the task entirely gratuitous and repaid only by criticism of his efforts.

A recent discussion anent the status of the clinical pathologist—or, perhaps, it were better looked upon as an initiation of a discussion, for the subject is not to be dismissed offhand by a dogmatic pronunciamento or two—forms no exception to the rule, but without discussion and the comparison of views and opinions, no conclusions can ever be reached.

It is customary, in philosophical discussions, at least—and it would seem as if the clinical pathologist must exercise a certain amount of philosophy in this matter—to clarify the preliminaries by some attempt to clearly define the subject matter, and it would be advantageous, therefore, to more or less succinctly determine if possible what is a clinical pathologist before attempting to assign to him offhand a classified niche in the practice of medicine.

That some such attempt is necessary is obvious, for even to the casual observer it is clear that there are many conceptions as to what constitutes a clinical pathologist, all very essentially modifying and effecting attempts at his classification. It is a common occurrence to note in the advertising columns of medical journals, for example, advertisements seeking "Laboratory technician; must be M. D.," evidencing at once that in that hospital, and in the minds of its directors, a pathologist is simply a person of more or less skill and training in the manipulation of laboratory apparatus.

This is not altogether surprising and capable of some explanation,

and methods of examination relatively few in number, and their indications and significance apparently clear and distinct. Possibly it was in those days that the idea of pathology as the "handmaid of medicine," instead of its colleague, first took root.

Those were the days when albumin in the urine meant "Bright's disease" and sugar diabetes. In those pleasant times every man was his own urologist and microscopist; he made his own examinations and determined their significance at will. Those without the time, or not caring to give it, sent their work to others who more or less restricted their efforts to those lines and whose function, as the practitioner saw it, was simply to make the tests and furnish him with a report.

With the evolution of scientific medicine, the scope and extent of laboratory examinations and technic broadened by leaps and bounds until, at the present time, unless by strenuous effort and continuous study and reading he manages to keep apace, the average individual soon finds himself lost in a maze of complexities. In fact, so numerous and so varied and so complex have the methods of laboratory study become that now even the laboratory has its specialized departments.

In the early, and even relatively recent, days the hospital laboratory, except in large and prominent institutions, was apt to be a somewhat forlorn corner in the basement or some place not especially desired by any other individual or department, and devoted to more or less routine examinations as dictated by the fancy or idiosyncrasies of the staff and the energy, ability, and initiative of the one in charge—too often, the resident physician, less often a more or less qualified technician.

At times, in order to gain a foothold in the hospital and as a stepping-stone to a future place on the clinical side of the staff, a younger man took the place as "pathologist," regardless of his primary desires or qualifications. Then came the movement for the betterment of hospitals and the establishment of the laboratory as an important and vital part of the hospital.

Forthwith, hospitals suddenly realized that laboratories must be equipped—particularly as regards personnel—and, likewise, that the supply of qualified and competent men was somewhat below the demand. With the usual eye to hospital expenses, salaries were not often of such proportions as to cause financial upheavals, and some reluctance and dismay grew out of the fact that pathologists could not be had for the same price as technicians, and some occasional surprise occurred to find that valiant pathologists now and then made their acceptance of positions contingent upon an equal footing on the staff with other staff physicians.

Not a little of the somewhat derogatory opinion held of the pathologist in some quarters may be laid to his willingness—often in a spirit of scientific endeavor—to accept positions with inadequate salaries and undignified standing, as regards his status on the staff. This is true of the present day in many instances. What other construction can be drawn when a great medical school, for example, advertises for a "well-qualified physician" who must be, it is stipulated, a graduate of one of several great universities, to take a position as whole-time patholo-

gist to an affiliated hospital for the astounding remuneration of \$2200 a year! Can it be wondered at that many hospitals not only offer inadequate salaries in return for the highest qualifications, but moreover, rule, in addition, that the pathologist shall not be allowed to see patients sent to him personally in consultation, and that when called to see patients in the wards or private rooms, with staff physicians, *his* status shall not be that of a consultant?

The difficulty is to understand why pathologists submit to such restrictions. Certainly, their status under such conditions is decidedly different from that of the surgeon or internist. In the endeavor to comply with the qualifications set up by hospital requirements, an important factor in the selection of a pathologist became, not what does he *know*, how fitted is he to correlate the work of the wards and the laboratory, but *how many kinds* of things can he do, how many different kinds of tests can he make? Technical and manipulative expertness became paramount, and the idea of the pathologist as a worker of tests was fostered and grew apace. A further helping hand to this conception was given by a certain proportion of physicians who look upon the test as the thing rather than its *interpretation*; who too often look upon the significance and interpretation of laboratory examinations as clear and simple, and who feel within themselves as omniscient competence, not only to select the most applicable and informative tests to be made, but, further, to announce in no uncertain terms its exact significance in the case at hand.

The status of the surgeon on the medical Olympus seems quite definite, and is easily ascertained on application; the status of the physician is not quite so clear. If by these latter are meant those who are especially trained and particularly adept in the diagnosis and treatment of medical conditions by medical means, their place in the sun may be more or less definitely determined; if, however, is meant the general practitioner who has progressed or catapulted into an office building, his exact status is determined, not by the fact that he deals with human beings—"variables"—but by his qualifications, scientific acumen, and ability.

It is somewhat difficult to see just why there should be any question as to the status of the pathologist or to be tolerant with discussion as to his place in medical practice. If recollection is not at fault, the great surgeons and many of those renowned among physicians founded their greatness upon a thorough training in pathology and pathological investigations. Was their clinical greatness achieved because or in spite of this, or did their knowledge and ability only commence with their initiation into the clinical world? Was their ability to make a diagnosis—upon which intelligent and successful treatment is always founded—aided or hampered by their training in things pathological?

NO FEAR OF CONTRADICTION NEED BE EXPERIENCED IF ONE LAYS DOWN AS A PREMISE FOR CORRECT DIAGNOSIS AND INTELLIGENT TREATMENT—EITHER MEDICAL OR SURGICAL—A THOROUGH KNOWLEDGE OF THE PATHOLOGY OF THE CONDITION. THE CLINICAL PATHOLOGIST POSSESSES SUCH KNOWLEDGE. WHEREFORE, THEN, IS HE OF LOWLY

STATURE UNLESS HE COUPLES A PRESCRIPTION OR TWO OR A METHOD OF TREATMENT WITH HIS LABORATORY FINDINGS AND THEIR INTERPRETATION?

Because "he deals with fixed substances." Let us contemplate this conception. This, perhaps, might be true of the technician—not of the pathologist who, if he is worthy of the name and possesses the confidence of his associates, certainly comes into close clinical and personal contact with the patient upon whom the tests are made and from whom test materials are secured.

The radiologist takes a picture, works with a multitude of "manipulations on fixtures and inanimate substances" most impressive to the uninitiated and yet, forsooth, is a respected and exalted member of the profession.

The serologist draws a specimen of blood and conducts a complement-fixation test—not an inspiring spectacle, to be sure, but one involving a most varied degree of skill and knowledge, and is looked upon askance. Wherein lies the difference? *The radiologist interprets his findings!* He is furnished with clinical data; privileged, when necessary, to conduct such examinations of the patient as are deemed of interest, and furnishes the clinician not only with the finished plate or film, but also with a statement as to the significance, in terms of the patient, of the picture presented. This seems to be the essential point of difference: The radiologist assumes, and is asked to assume, the responsibility for the interpretation of his findings, while the privilege is largely denied to the pathologist who is looked to simply for the report.

Now it is impossible to deny, if one is at all conversant with the subject, that it is not the making of the test, but its interpretation, its significance in terms of the particular case which is of value.

Technicians may be taught to perform various manipulations, sometimes of intricate and complicated character, but the end-result is simply a completed test—no more. The informative value of the test lies in its interpretation, and for that the technician is not qualified. For that is required a varied and extensive training, not only in pathology and immunology and a host of allied and related subjects, but, in addition, the training, skill, and experience and ability to read the results by a combined estimation of all the findings evaluated by observation, deduction and inferential reasoning concerned, not only with the test, but with the patient!

It seems to be more or less generally admitted—sub rosa at least—that the physician in general is not as well qualified as the radiologist to read and interpret the significance of x-ray pictures. It seems to be a more or less common conception, also, that anyone can read and interpret the results of laboratory examinations. The correctness of this last assumption seems open to discussion.

From the standpoint of the laboratory worker, cognizant of the number of laboratory reports which may be added to the patient's chart because of the extensive area now covered by the various methods of laboratory examination, it would seem that there is an all-important difference between the employment of laboratory methods and their clinical utilization.

No one is more quick than the clinical patholo-

gist to note that the development of laboratory methods has had a tendency to detract from clinical acuteness in the study and analysis of the patient; to develop a tendency to demand of laboratory methods that they shall render unnecessary the, perhaps, arduous and at times burdensome analysis of the history and the results of a painstaking meticulous, thorough, and minute physical examination. This I have previously noted (*Journal A. M. A.*, May 13, 1922), together with its effect upon the decadence of observation as a clinical art, and attention is again called to this by Conner in an able and timely paper in which he pleads for "an effort on the part of all of us to resist and counteract the growing inclination to regard the use of laboratory and instrumental aids as the chief means of diagnosis, and to give too little weight to the more laborious but more important measures of painstaking clinical observation and careful deductive reasoning." In other words, he pleads for the *intelligent* use of the laboratory as a *phase* of the examination of the patient and the interpretation of the findings in the light of *all* the information obtainable, thus emphasizing that the laboratory is most useful and informative to those by whom it is intelligently and not blindly used.

There always has been discussion as to who shall interpret the laboratory reports. As I have stated elsewhere (*Med. Rev. of Rev.*, 1922): "Theoretically, the physician, as the one in close contact with the patient, should be the interpreter; actually, however, for even the laboratory finds itself divided into highly specialized departments, unless he be a man of exceptional training and experience, fortified by extensive reading and a retentive memory, it is almost impossible for the physician of today to be familiar with all the resources of the clinical laboratory of today."

THE QUESTION ULTIMATELY RESOLVES ITSELF INTO THIS: SHALL THE CLINICAL PATHOLOGIST BE PERMITTED—EVEN REQUESTED—TO ASSIST IN THE INTERPRETATION OF LABORATORY REPORTS ON THE ASSUMPTION THAT HE IS—OR SHOULD BE—WELL QUALIFIED BOTH FROM THE LABORATORY AND CLINICAL STANDPOINT TO EVALUATE THEM, OR SHALL THE INTERPRETATION OF LABORATORY REPORTS BE CONFINED SOLELY AND ENTIRELY TO THE CLINICIAN BY "DIVINE RIGHT," AS IT WERE, AND THE PATHOLOGIST BE SIMPLY THE INDIVIDUAL FROM WHOM THEY EMANATE?

This latter assumption concedes or attributes to the clinician *in general* an omniscient ability in this respect. However, when the clinical pathologist, as he does, observes the diagnosis of syphilis cast aside because of a single negative serologic report; or that a negative blood reaction is a source of amazement in the presence of neurosyphilis; when he is constantly appealed to as to the reason for and significance of an anti-complementary report; when he observes the more or less complete reliance placed upon the total white cell count in a suspected infection; the importance given to an isolated gastric analysis; the administration of bacterial vaccines in daily doses; requisitions for malaria, but neglect of the total white count when the patient has had a chill; the surprise that an agglutination test could be negative in the presence of undoubted typhoid

fever or the dismissal of this possibility because of a negative reaction; the fact that more laboratory tests are ordered for the corroboration of preconceived ideas than for their purely informative value; the lack of evident motive for the requisition of whole flocks of non-related laboratory tests difficult, to say the least, to correlate with the clinical findings or history, and the not infrequent tendency to consider exhaustive clinical or historical data unnecessary if there is a laboratory test applicable to the condition—confronted with these and other experiences common to all laboratory workers, it is not to be wondered at if the clinical pathologist at times has a fleeting doubt if *all* clinicians are able to utilize the laboratory to its fullest extent; or that the mechanism leading to the production of various positive reactions is *always* clearly understood and their clinical significance quite clear.

It is a safe statement to make that the intelligent practice of medicine demands an intelligent conception of the structure, physiology, and pathology of the part one essays to treat. The best clinician, be he surgeon, physician, or what not, is he who has the pathology of the condition at his finger-tips.

Although the clinical pathologist per se does not treat disease, it can be safely suggested that, knowing the pathology of the condition; the mechanism resulting in the manifestations which constitute its symptomatology; the methods of estimating the degree to which, as a result of the condition, functional efficiency is disturbed and the particular function impaired, together with the general resources at hand to combat these effects—although, perhaps, the pathologist might not be prepared to dash off a prescription or two offhand, it is quite likely that the measures he would ultimately suggest would be rationally conceived. It is not likely, for example, that he would prescribe expectorants in the stage of consolidation in pneumonia nor expect much from their use. If he deals only with "inanimate substances," with test tubes and reagents, he is not a real clinical pathologist. The real clinical pathologist is a doctor of medicine, with the same training as the surgeon or physician; equally well grounded in the clinical arts, and, moreover, particularly adept in the specialized manipulations of his chosen specialty, and able to interpret in terms of the patient the pathology he demonstrates in the laboratory.

He is a man who is capable not only of conducting various laboratory manipulations, but also by virtue of his special training, his reading, and his correlated laboratory and clinical experience, to apply them to the diagnostic problems at hand and, what is quite important, to select from those available, those which are likely to be informative. He is closely concerned with the treatment of disease as governed, and at times even indicated, by laboratory procedure. He should be, as has been said, the man who knows the most about disease.

He is the one to whom the thinking clinician, more interested in the welfare of his patient than the magnification of his dignity, can say: "Here is the patient. These are the clinical findings. This is the history. What can the laboratory do in the interests of this patient and his return to health?" And only when such a clinician and such a patholo-

gist put their heads together are the interests of the patient best conserved.

The real clinical pathologist not only sees the test, but he also sees the patient and applies, not only his laboratory, but his clinical knowledge as well to a consideration of the problem. He works not for but *with* the clinician and, sometimes, when he steps over into the clinical world and becomes a physician or surgeon, he finds his status in that sphere readily established and not a whit impaired by his previous specialization in another sphere.

It is, perhaps, true that it is not the pathologist's duty to make the diagnosis for the clinician, but rather to supply him with informative data. It is equally true that there are times when the data requested by the clinician are neither informative per se nor apt to be made so by the interpretation put upon them. Under these—and, indeed, under all circumstances—the true status of the clinical pathologist should be evident: he should be openly, as he often now is indirectly, a consultant.

DISCUSSION

M. C. TERRY, M. D. (Consolidated Building, Los Angeles)—I agree with Dr. Kilduffe that the clinical pathologist is a physician with the same training as the surgeon or internist, but I do not think he is equally well grounded in the clinical arts. If he were all that, then the thinking (and conscientious) clinician would endeavor to become a clinical pathologist himself, or he would say to the pathologist, "Here is the patient—take him," and we should soon have no pathologists. The clinical pathologist is a specialist, as Dr. Kilduffe has also said; let us recognize the limitations implied.

He should, of course, keep in touch with the clinic and with clinicians, the better to understand and explain to others the significance of his own work, for the new ideas such contact produces and for material for whatever special problem he may have in hand. But it is fortunate for him that his time is not often required for bedside consultation, even in cases in which a considerable amount of laboratory work is done. To a great extent he can choose his own consultations of this sort—true, without pay, as a rule.

The real clinical pathologist has few days without consultation in his laboratory or over the phone, and these are generally sufficiently clarifying for both the clinician and the pathologist. True, again, the pathologist seldom gets paid for this very real service, and that seems hardly fair, but here the pathologist's troubles are a part of the general social problem of medicine, and the solution of that problem is hardly in sight.

JOHN W. SHUMAN, M. D. (Westlake Professional Building, Los Angeles)—Pathology is an integral part of medicine. It embraces bacteriology; it functions diagnostically and therapeutically in the laboratory upon material things, pre and post-agonal, pertaining to the human being. The term "clinical" pertains to bedside or clinic. The doctor of medicine who devotes most of his time and energy to pathology always has been and still is termed a pathologist; usually he is very weak along clinical lines. The doctor of medicine who devotes most of his time and energy to the study of subjective and objective signs and symptoms of disease at the bedside has always been and still is called a clinician; he, too, frequently is not well versed in pathology. It is logical to call an M. D. who is wisely interested in pathology and clinical medicine a clinical pathologist; he could be called a consultant in medicine. There is no more excuse for a well-informed consultant in medicine to misinterpret an x-ray series of the gastro-intestinal tract than there is for misinterpreting fecal vomiting or for his failure to recognize a malarial parasite than there is for him failing to recognize an enlarged spleen.

It is not the status of the clinical pathologist that we should discuss, but the status of clinical pathology. Kilduffe is quite right in reference to his "three prehistoric

groups as they used to be." I may add they are still with us, but in closer harmony. I have no regard for that dangerous type of surgeon who would submit a piece of tissue without complete data to the pathologist, demanding a diagnosis. Happily, this method of procedure is being changed, and it is the clinician working with his pathologist and with the best interest of his patient at heart that has brought about the changes. Today the status of clinical pathology is that the up-to-date physician must know and be able to do "his stuff" diagnostically and therapeutically better than he ever did it before. The public demands it. Diagnosis calls for the same use of clinical methods which entail dependable laboratory procedures, all of which must be supervised and correlated by the doctor who is managing the patient, and his consultant.

Kilduffe's discussion is a most thorough outline for a consultant in any branch of medicine. The paper is well written, and is a fine exposition of the idealistic status of the clinical pathologist. Any individual who aspires to become well versed in clinical pathology may well study his article.

ELMER W. SMITH, M. D. (St. Mary's Hospital, San Francisco)—I agree most thoroughly with most of Dr. Kilduffe's article. The physicians and the hospital staffs have been relying so long upon the advice and reports of the lay technician, unsupervised by a medical man, that they naturally would be inclined to place the man with the M. D. degree who does similar work in the same class. I feel that the clinical pathologist, especially one connected with a hospital, should not be expected to do the ordinary routine work. Technicians can readily be trained to do this work in a short time, and in some cases do it more dexterously than the pathologist himself. He should see the reports and have their interpretation in hand so that he can intelligently discuss the case in hand with the physician or clinician in charge. His services as consulting pathologist or clinical pathologist should merit the same evaluation as that of the consulting clinician. The real clinical pathologist should have time to read, to visit other laboratories for new and supplementary methods, etc. The clinical pathologist is expected to know something on practically every phase of medicine. He is called in for consultation by every specialist from the eye to the genito-urinary specialists, yet his services, in the past at least, have not commanded the same recognition either financially or professionally.

Nowadays there are too many requests of the laboratories for a "diagnosis" rather than a report that will help lead to a diagnosis. I agree with Kilduffe that a proper diagnosis requires the use of our common observations or "senses," as well as laboratory reports; yet in many instances the clinical pathologist, or even the lay technician, is expected to form a diagnosis without one iota of information about the patient. One actual case illustrates this: A physician sent to a pathologist a bit of mucous membrane, requesting a *diagnosis*, without one bit of information regarding the source of the material or any other data. The clinical pathologist does not possess supernatural intelligence, nor should such be expected of him. He should be treated as a fellow practitioner on an equal basis, in a common cause, working for a common end: namely, the diagnosis of the disease and a study of the progress or trend of the same.

E. H. RUEDIGER, M. D. (Angelus Hospital, Los Angeles)—Clinical pathology in the broadest sense of the term really includes everything pertaining to illness except the treatment. A clinical pathologist should be a graduate in medicine and SHOULD BE LICENSED TO PRACTICE MEDICINE. ON SEVERAL OCCASIONS COURTS HAVE RULED THAT DIAGNOSING DISEASE MEANS PRACTICING MEDICINE, AND ANY PERSON NOT LICENSED TO PRACTICE MEDICINE WHO DIAGNOSES DISEASE AND CHARGES A FEE FOR SUCH SERVICES IS GUILTY OF PRACTICING MEDICINE WITHOUT A LICENSE. The clinical pathologist frequently makes diagnoses. For instance, a tumor is sent to him for *diagnosis*. In diphtheria, tuberculosis, malaria, typhoid fever, leukemia, and in many other conditions the diagnosis is frequently made in the laboratory, and a positive diagnosis is usually impossible without laboratory aid. It may be argued that the clinical pathologist acts under directions of a licensed clinician, but this is not tolerated legally and should not be

ethically. Under existing laws a surgeon may not remove appendices, thyroids, unless he is licensed to practice medicine and surgery, even if such an operation is requested by someone who is so licensed.

At the present time there is not enough co-operation between clinician and clinical pathologist. Usually the clinician is to blame. He does not seek advice because he wants all the credit for making the diagnosis. On this point I have seen clinicians go so far as to forbid the clinical pathologist from making the diagnosis of tumors. The clinician demanded a description from which he could make his own diagnosis.

For the benefit of medicine and for the benefit of the patients, clinicians and clinical pathologists must work together. Progress in medicine will be impossible unless clinical findings and laboratory findings are carefully compared, and to that extent the clinical pathologist should be a consultant.

WILLIAM FITCH CHENEY, M. D. (Shreve Building, San Francisco)—In a busy world like ours it scarcely seems worth while to spend time discussing the relative importance of individual workers. A man ought to be judged in the medical profession, as in any other vocation, not by the position he holds or the income he receives, but by the quality of what he produces. Whether his work is done in hospital wards, at patients' homes, in laboratories or operating-rooms, *the object of each and every member of the medical profession should be service to humanity; and his ambition should be to do his work with the maximum of benefit to those who entrust themselves to his care.* What difference does it make where the work is done, and who shall decide that one place of work is more honorable than another? *If we all try at all times to be just to one another, as well as to those outside our profession; if we walk humbly, without undue estimation of our own importance in the scheme of things, there will arise no occasion for belittlement of any man's work because we consider it of less value than our own.* We need one another's help, and we cannot get too much in the effort to solve our problems; and the only true measure of another man's worth is not the character of his contribution, but the thoroughness, the intelligence, and the honesty with which he does his part.

WILFRED H. KELLOGG, M. D. (State Hygienic Laboratory, Berkeley)—I believe Dr. Kilduffe has, in the main, the right idea regarding the proper place in medicine of the clinical pathologist, and that in the future it will be recognized more than at present that the field of clinical pathology is essentially a specialty of medicine. At the present time the idea that laboratory procedures are comparatively simple and are of such an exact nature that any so-called technician is competent with a few weeks' experience to be entrusted with the responsibility of a diagnostic laboratory is entirely too prevalent. Strange to say, many physicians who appreciate fully the necessity of education and careful training for themselves will lightly employ anyone who claims to be a "bacteriologist" without further investigation. I have more than once received requests from physicians that I take their office nurse for a couple of weeks' training so that they can do Wassermann tests. *The woods are full of this "domestic servant type of technician," and it will require not only education, but something else to correct the situation, fraught with danger as it is to the patient, to the reputation of the doctor and to the esteem in which a very important part of the practice of medicine is held by the rest of that profession.*

For the purpose of protecting the physicians of this state, of aiding good laboratories to maintain their excellence and of helping those not so good to raise their standards, the State Board of Health has, through the State Hygienic Laboratory, instituted a system of inspection and approval of diagnostic laboratories. The procedure is largely voluntary on the part of the laboratories, and has been received with a cordial welcome by the true clinical pathologists of the state. Those laboratories that have the proper equipment in personnel, apparatus and technic used for the work they are doing are given an official certificate of approval. The inspection does not at present cover tissue diagnosis or bio-chemistry, as these seem outside our field, which is that part of the clinical pathologist's activities having to do with the pub-

lic health. *To date, about forty-five laboratories have been certified, and physicians should look for this certificate on the wall of the laboratory they patronize.*

WILLIAM OPHULS, M.D. (Dean Stanford Medical School, 2398 Sacramento Street, San Francisco)—I have read with the greatest interest the manuscript of the article by Robert A. Kilduffe on "The Status of the Clinical Pathologist." It appears to me that Dr. Kilduffe has presented this subject very well, and that the discussion covers all aspects of the situation. I, therefore, have nothing further to add to this symposium, and I am herewith returning Dr. Kilduffe's manuscript.

L. S. SCHMITT, M. D. (Acting Dean University of California Medical School, University of California Hospital, San Francisco)—The yard-stick with which to measure relations between medical units of whatsoever nature is the benefit derived by the patient. To obtain the greatest benefit, this relation must be characterized by co-operation and team work. Individualism must be submerged.

In order that the best service be rendered to the patient, some one person must be charged with the conduct of the medical service rendered. Obviously, this should be the attending physician or surgeon.

If we accept, as a premise, that the clinical pathologist is a physician skilled in laboratory technique and the interpretation of laboratory procedures, to obtain the desired team work he must have a knowledge of the patient's condition. To do so, he should be versed in the art of clinical observation, but he should also know the uses and abuses of laboratory procedures. If this makes him a "consultant in medicine," it is a change in nomenclature rather than in conditions.

Therefore, the status of the clinical pathologist, as expressed in Dr. Kilduffe's paper, should be that of a specialist to be called upon by the attending physician or surgeon when needed to complete the team and secure the greatest amount of service for the patient.

NEWTON EVANS, M. D. (President College of Medical Evangelists, Loma Linda, California) —The perusal of the paper and the discussions has been most stimulating. The position of the clinical pathologist in the medical profession is a subject needing study, and the essential points in the solution of the problem have been clearly presented. When one approaches the problems with a realization of the paramount importance of the greatest good to the patient, the personal standing of the clinical pathologist will necessarily become a secondary matter.

In my opinion the physician who has, by his earnest work in pathology and laboratory procedures, reached a position of eminence in the medical profession, commands the highest respect. To the young physician the career of the clinical pathologist, for obvious reasons, is comparatively unattractive. In working to a place of prominence in this field he does not have the incentive of the larger income or popular acclaim which come to the surgeon or other specialist or to the general practitioner. In the face of these difficulties the physician who makes his place in the profession as a pathologist is worthy of honor.

RENE BINE, M. D. (San Francisco)—What is a clinical pathologist and what should be his status in medical practice, Kilduffe asks, and so do many others, without apparently reaching an agreement.

The general practitioner looks upon the pathologist—or should—as an individual who has specialized in one branch of medicine—as a consultant to be made use of and called upon to assist whenever, in the course of his professional work, he finds that he requires counsel or assistance in the specialist's chosen field.

The specialist, regardless of his field, must *show* that he can be of help before the general practitioner will call upon him, and the wisest doctor is the one who, knowing his own limitations, is big enough at all times to admit them to himself, his patients, and his colleagues.

In a hospital, where every opportunity for team work exists, the pathologist should have no trouble in receiving the recognition Kilduffe strives for. But his status will depend not upon his title, but upon his ability, personality, and tact. This means a diplomatic attitude toward those of the staff who are not big enough to avail them-

selves at once of his skill, but who can usually be finally won over. It took time for the children's specialist to show that he knew a little more about children than most of the mass of physicians, and so has it been with the ophthalmologist, the aurist, the orthopedist, the radiologist, etc., etc.

In our battle against disease let us make the best possible use of all our resources, and let us not fight to see whether it was the surgeon or the physician or the bacteriologist who "won the war" and "who has priority in the collection of indemnities"; medical historians or patients or whoever cares will decide that soon enough, rightly or wrongly. Do not waste energy telling anybody what he should not do; either help him do it, or show him modestly and tactfully how much better you can do, in the hope that in time he will look to you for that co-operation which you yearn to give him.

A. W. HEWLETT, M. D. (Professor of Medicine, Stanford Medical School)—Dr. Kilduffe, in his interesting paper, has again called attention to the changing conditions of medical practice. More and more the physician in charge of a patient must depend upon others for data concerning the pathological conditions with which he is dealing. X-ray examinations, clinical laboratory reports and examinations by specialists must be accumulated and interpreted in the light of the patient's symptoms. As a rule, the physician in charge can best interpret the various findings, for he is familiar with all aspects of the case. In certain instances the laboratory worker, roentgenologist or specialist may see a meaning in his findings which would escape the physicians in charge, or he may be able to suggest further examinations which might clear an obscure problem. It is plainly his function to furnish this guidance, either as a comment on his report or after making himself familiar with the patient's general condition. But it is difficult to formulate any rule which will apply to all types of clinical laboratory. For the time being it seems to me that the clinical laboratory should be allowed to develop without restrictive rules. Capable men who have something to offer beyond the usual routine will become recognized, and they should be properly compensated.

WILLIAM J. KERR, M. D. (Associate Professor of Medicine and Acting Head Department of Medicine, University of California Medical School) —Specialization in medicine has led to a variety of difficulties, both for physicians and such workers as have been developed to carry on special lines as adjuncts to the work of the physician. It does not seem that there is any clear solution to many of these difficulties. The complexity of the situation has resulted in much dissatisfaction from the standpoint of the public, and a great deal of controversy among physicians. In the beginning the physician who did the more or less simple procedures in the study of his cases was a better physician, because he could apply these findings directly to the problem at hand. As the procedures which may be used in the study of a given case have multiplied and require the skill of those who are specially trained in their manipulation, it has not been possible for the physician or surgeon to devote the time or the study to the technical details. These details, however, may be mastered by those without a medical training; they may be carried on under the direction of a physician who, with his further training and knowledge, may apply the findings to his work without detriment to the patient. However, such technical assistants can seldom be relied upon for interpretation of the findings and must work in close co-operation and association with the physician. There is such a diverse group of individuals who are doing clinical pathology, either as assistants to physicians or as assistants in a general, private or hospital laboratory, that there can be no set standards as to qualifications or salaries at the present time. There are relatively few physicians who set themselves up as clinical pathologists and supervise the work in large laboratories. To my mind, such workers should be on a salary which is ample to provide for the necessities of life, depending upon their training and ability.

It is natural that one who has had a clinical training and can carry on this work must be called upon frequently for interpretation of findings. This might mean a consultation in a given case, but for the average case, or the great majority of cases under consideration, a bed-

side consultation would not be required. Such a clinical pathologist would be of great service to the clinician, and would at the same time improve his knowledge of clinical matters. He should not feel belittled in the knowledge that he is assisting the clinician in solving the problems at hand; he should delight in the fact that he is developing a field of medicine which, due to the great specialization in recent times, has become necessary. It is quite obvious to me that if the clinical pathologist should feel he must be called into consultation at the bedside frequently, he would soon have practically no time to supervise the work in his department. He would be less and less a pathologist and more and more the clinician, and sooner or later would have to choose as to whether he would devote his time chiefly to the laboratory or chiefly to the bedside. He would soon find the situation intolerable, and because of the possible increase in income would probably become a pure clinician. It is not to be denied he might be a better clinician than his fellows because of his training in clinical pathology, but the physician is not worthy of the name unless he keeps abreast of the work in clinical pathology and is able to apply the findings to the problems at hand. He may do many procedures which are more or less routine which are done as a protection to himself and the patient, but he should always see abnormal specimens or findings for his own education and as a further protection to the patient and to himself. Anyone who relies entirely on the laboratory, whether the work be done by a technician or a clinical pathologist, without frequently seeing the results of the tests himself and being able to interpret them at the bedside, is not a physician of the highest type and should be discouraged. The great interest at the present time in laboratory work has led to excesses in the amount of work done with great economic loss to patients. If we as physicians could be more thoughtful of the limited number of procedures which might be used with profit in a given case, we would better serve both the patient and ourselves in solving his problems.

STANLEY STILLMAN, M. D. (Professor of Surgery, Stanford University Medical School, San Francisco)—Dr. Kilduffe's paper is timely and very rightly calls attention to a situation to which not enough thought has been given. There is a growing recognition of the value and need of obtaining the advice and opinion of the clinical pathologist in a large number of cases. In fact, in many institutions and among many groups of clinicians such consultations are frequent. A notable instance is the prominent part taken by Professor Kolmer in the case of President Coolidge's son. Again, it may be noted that at St. Mary's Hospital in Rochester the clinical and pathological laboratories are in close relation to the operating departments. In a number of other institutions also steps have been taken to make the laboratory and the clinical pathologist more accessible. In many of the older hospitals the clinical and pathological laboratories were placed in remote and almost inaccessible situations, and the clinician was not expected, either as a visitor or for purposes of consultation and discussion.

The situation is changing, and it is a desirable thing to hasten the day when the clinician and laboratory man shall work in closer relationship. The rapidity of the change depends largely on the attitude of the laboratory worker. If he desires to broaden his work and develop his interest in the practical application of his laboratory findings with reference to symptoms, diagnosis and therapy, his knowledge will be widely sought on a consultation basis without in any way interfering with the field of the clinician.

The clinical pathologist is presumed to be a man thoroughly educated in all branches of medicine. His chosen specialty should not take him so far afield as to separate him completely from the clinician. Contacts should be made and maintained not alone through the practitioner, but through diagnostic groups and clinical societies. If discussions of the practical application of laboratory findings by radiologist, bacteriologist, pharmacologist, pathologist, serologist, and metabolist were more common, the inclusion of these specialists in consultation work would rapidly spread.

GERTRUDE MOORE, M. D. (Director Western Laboratories, 2404 Broadway, Oakland)—To my mind the train-

ing and aptitude of a clinical pathologist should be both that of a medical technician and a clinical diagnostician. He is the man who knows and supervises the detail of the laboratory, and is at the same time familiar with the strictly clinical side. He is, therefore, the one, before all others, most able to determine tests indicated, to supervise the details of their manipulation and, most important of all, to interpret their meanings in terms of pathology existing in the patient. It is his duty to advise in the use, and method of administration, of certain therapeutic measures. I, therefore, believe that he is in the truest sense a consultant, whether he meets the attending physician at the patient's bedside, in the laboratory, or discusses the case over the telephone. He is the man to whom the worthwhile practitioner looks for aid. In my experience, such consultations are common. They may not be called by that name, and some may bring little financial reward, but they are none the less real consultations, and the clinician is daily realizing more and more their value to him. The time is past when pathology is looked upon as a lowly calling. In my community the pathologist is accorded the same honors and the same consideration by organizations and individuals as is accorded any other member of the profession.

F. R. NUZUM, M. D. (Santa Barbara Cottage Hospital, Santa Barbara)—Dr. Kilduffe's paper points out the uses to which the clinical pathologist and the clinical laboratory should not be put. I believe that these abuses are rapidly becoming much less frequent. I also believe that a proper relation between the clinical pathologist and clinical men is rapidly being reached.

The clinical pathologist must be supplied with sufficient data to give a proper interpretation to any of his findings. The competent clinician does not scorn assistance from the clinical pathologist. He profits through his association with such a man, and in this manner makes himself proficient in the proper evaluation of laboratory work.

In the organization of hospital staffs, proper emphasis must be placed upon these matters, so that men likely to misuse the clinical laboratory in their work may become properly educated.

WALTER V. BREM, M. D. (Pacific Mutual Building, Los Angeles)—It is difficult for a clinical pathologist to discuss the status of clinical pathologists without speaking from his own experience, and in speaking from his own experience he may reveal an unenviable attitude of mind—either an undue egotism or an inferiority complex.

However, I will venture to say that, although we have met with some confusion regarding the place of pathology in the practice of medicine, there has never been any question regarding our professional status, either on the staffs of various hospitals or in the different medical societies, and we have been called in consultation, remunerative or otherwise, as often as is good for our laboratory work. We feel, therefore, that the medical profession has been more than generous, and we believe that the status of the clinical pathologist is a question of personal equation.

We do feel, however, that the problem of stimulating high-class men to specialize in pathology is a much more serious and pressing problem. Indeed, adequately trained tissue pathologists are becoming more and more scarce, and fewer physicians are choosing pathology as a specialty. The reason for this is that the importance of pathology, especially tissue pathology, is not recognized sufficiently well to cause provisions to be made for the adequate compensation of pathologists, that is, for compensation commensurable with that of his clinical colleague of equal ability. Moreover, when efficient and honest laboratory service is available many physicians and surgeons send their work elsewhere because of smaller fees or direct or indirect rebating. This tends to depress the fees of the real pathologist, fees which are already too small, or tempts him to indulge in unethical practices.

Of course, this situation renders the field unattractive for men of the highest ability. When such men are induced to specialize in pathology there will be no question of status.

A. M. MOODY, M. D. (St. Francis Hospital, San Francisco)—I have carefully read the article by Dr. Robert A.

Kilduffe on "The Status of the Clinical Pathologist," together with the appended discussions.

Experience has taught me that it is not only impossible, but impractical for a medical director of laboratory work to spend the amount of time in clinical work necessary to make him really proficient in things clinical, without being correspondingly neglectful of his duty as pathologist.

The degree of helpful application of any medical man's experience, in whatever branch of medicine he may be practicing, will alone determine the status of that individual.

DOCTOR R. A. KILDUFFE (closing)—The main purpose of the paper was not to present any set or individual viewpoint, but to arouse discussion of a problem meriting attention.

Those familiar with the trend of current discussion of medical education and medical practice cannot fail to appreciate that neither have as yet attained the ideal; nor can it be gainsaid that the fullest clinical utilization of laboratory resources as a part of the clinical study of disease is the exception rather than the rule—whether one considers the recent graduate who, too often, looks upon laboratory examinations as the *sine qua non* of clinical study, or the older practitioner who may either give them an unwarranted significance or more or less disregard them entirely.

Laboratory and clinical medicine are not distinct entities; one is complementary to the other. The clinician must know enough of laboratory medicine, of pathology, to utilize its methods wisely and to the best advantage. The pathologist must be sufficiently a clinician to interpret in terms of the patient the abnormalities he demonstrates in the laboratory.

It is well, indeed, to commend the thoroughness of one's colleague and the integrity of his efforts; but it is better to be eager and able to utilize them to the fullest extent.

If the entrance of the laboratory, as personified by the pathologist, into the wards or the problems of clinical medicine as an active participant in their attempted solutions is to be looked upon as an intrusion, then all that is necessary is a sufficient number of technicians to handle the work. It seems more sensible and more conducive to success in the efforts to solve the clinician's problems to expect and demand of the pathologist that he be something more than a manipulative expert. A clear understanding of the situation demands a preliminary clear and distinct differentiation of the pathologist from the technician.

It must be recognized that clinical pathology is a specialized branch of the practice of medicine, and that it is neither limited to nor comprised in the mechanical and more or less automatic performance of technical manipulations in the form of tests. There is some reason to maintain that in the minds of some, at least, the conception of clinical pathology has been limited to tests of one sort or another, and of the pathologist as the performer of tests.

Ewing summarizes the function of the pathologist as:

"1. To investigate the causes of fatalities . . . to elucidate the causes of disease . . . and to correct partial or erroneous diagnoses.

2. To keep himself familiar with the literature and progress of the medical sciences.

3. To co-operate with the internist in general diagnosis and to serve the surgeon in gross anatomic and physical diagnosis.

4. To serve as a consultant in the wards and the operating-rooms where, by virtue of his special knowledge, he should be able to bring data with which, as a rule, the clinician is less familiar.

5. To supervise the work of the clinical laboratory . . . restraining excessive demands, establishing correct indications for the resort to laboratory tests, and aiding in clinical research."

Doctor, if that addict you prescribe for happens to be a detective, you are in trouble with the law.

If he is not an under-cover agent, but another who really should not have the drug, what about your conscience?

GLUCOSE INTOLERANCE ASSOCIATED WITH ECZEMA

By SAMUEL AYRES JR., M. D., Los Angeles

(From the Department of Dermatology, White Memorial Hospital)

A preliminary report is presented, dealing with the glucose tolerance reactions in a series of thirty-six consecutive cases of typical eczema.

The tests were made in two laboratories, each using the Folin-Wu colorimetric technic.

The fasting blood sugar values in these cases of eczema were not found to be abnormally high except in a few cases.

Very striking deviations from normal were found, however, at the one and two-hour periods, following the administration of the test glucose solution. Of the thirty-six eczema cases, 33.3 per cent showed 200 mgs. or more of glucose per 100 cc. of blood at the end of one hour in contrast with only 5.6 per cent of 300 normal controls, and 16.6 per cent of the eczema cases showed 200 mgs. or more at the end of two hours in contrast with only 0.8 per cent of 253 normal controls.

Of the thirty cases which were tested at the end of three hours, 40 per cent had not returned to a conservative estimate of normal (110 mgs.).

Important discussion by Oscar V. Schroeter, Los Angeles; Kendal P. Frost, Los Angeles; Lorena M. Breed, Pasadena; George Piness, Los Angeles; H. P. Jacobson, Los Angeles.

REPEATED attempts to discover the cause of eczema have led gradually to a realization of the fact that there is no one cause. The conception of eczema as a symptom, rather than a disease entity, is helping materially in solving the riddle of its causation. No one regards abdominal pain as a disease; it is merely a symptom of one out of many possible causes. The mechanism by which the pain is produced, namely, stimulation of the visceral or peritoneal receptor nerve-endings, with passage of the impulse to the brain and frequently to the corresponding cutaneous area, is the same in many conditions. Thus, an acutely inflamed appendix, a gallstone, a tabetic crisis, or a green-apple "tummy-ache" may produce the symptom of abdominal pain, although there will be certain variations in its location, intensity, quality, etc. In the same manner, apparently, a number of causative factors, may, through the medium of the cutaneous vaso-motor system, produce the symptom which is commonly recognized as eczema. Sensitization to the proteins of certain foods, pollens, animal emanations, etc., classed together as allergy, constitutes one of the major causes of eczema. Improper utilization of fat, especially in infants, has been claimed also to be causative in a certain proportion of cases of eczema. The substances which may produce an eczematous reaction through local irritation are too numerous to mention. Poison oak, lacquer, dyes, chemical agents of all kinds, are some of the more common examples.

Disturbances in carbohydrate metabolism have long been recognized in a half-hearted way as being responsible for, or at least associated with, eczema in a few instances. Practically none of the textbooks on general medicine, even in the chapters on carbohydrate metabolism, make any especial mention of eczema as a possible manifestation of a dis-

turbed carbohydrate metabolism, and the current texts on dermatology are equally silent on this point.

The first scientific work of any importance establishing a relationship between eczema and disturbed carbohydrate metabolism was the recent report by McGlasson on the fasting blood sugar in a series of 158 cases of assorted dermatoses, mostly of an eczematous type. Of the entire series of 158 cases, 139 cases, or 87.9 per cent, gave fasting values of 120 mgs. of sugar or more per 100 cc. of blood. Between 90 and 100 mgs. would probably be considered an average normal reading. McGlasson groups his cases according to the clinical appearance at the time of examination. Thus, of the group of 44 cases of seborrheic dermatitis, 77.3 per cent gave readings of 120 mgs. or more; in the flexural dermatitis group, comprising 32 cases, 90.6 per cent were at 120 or above; in the "toxic rash" group of 39 cases, 87.2 per cent showed values of 120 or above, and in the group of 22 cases showing vesicular eruption of the hands, feet, and crotch, 77.2 per cent were above 120 mgs.

All of McGlasson's sugar determinations were made in one laboratory, using the Gradwohl gravimetric method in the majority of the cases, although Gradwohl's modification of the Lewis-Benedict colorimetric method was used in many of the cases. Both methods were used simultaneously in ninety tests with very close agreement between the two methods, the average for the gravimetric being 133.4 mgs. against 135.2 mgs. for the colorimetric method. McGlasson found that many of these cases improved rapidly on a low carbohydrate diet even when no local treatment was applied.

The present study was undertaken in order to examine in more detail the nature of the carbohydrate metabolism in typical eczema. The exact definition of what constitutes "typical eczema" is rather difficult, since an eczematous eruption, if untreated, may pass through a number of phases, sometimes as many as six or seven. Thus, there may be at first simple erythema; later, edema; then vesiculation, exudation, crusting, and, if the inflammation subsides, desquamation; or if the inflammation continues in a subacute form, thickening or lichenification. The alterations brought about by treatment proper or improper, and by occasional pus infection, still further complicate the picture. It does not seem possible that any one phase can be singled out as typical eczema in contrast to the other phases as atypical. Nor does it seem rational to classify too sharply cases of eczema according to the stage in which they are seen. Possibly a month or a year later they may be in entirely different stages.

With these facts in mind it will be seen that erythematous, vesicular, oozing, or lichenified types are included in this series as representing cases of typical eczema, but cases frankly not eczema, such as erythema multiforme, seborrheic dermatitis, or dermatitis herpetiformis, are not included. The tests were made routinely on both private and clinic patients whenever they could be persuaded to submit, and aside from the above restrictions no attempt was made to select the cases. On the other hand, every effort was used to make this series one of consecutive cases, so that the results would definitely

indicate the extent to which disturbed carbohydrate metabolism was associated with eczema.

The glucose tolerance reactions were tested in thirty-six consecutive cases of typical eczema. The cases were distributed between two laboratories, the laboratory of Drs. Brem, Zeiler and Hammack, and the Metabolic Research Clinic of the White Memorial Hospital, each using blood obtained by vein puncture, and each employing the Folin-Wu colorimetric technic. The test meal consisted of 1.75 gm. glucose per kilo of body weight in 300 cc. water, administered in the morning fourteen hours after the last meal; in a very few cases the test meal consisted of 100 gms. of glucose, without regard to the weight. The analyses of the two laboratories showed a general agreement.

A striking difference is noted in the fasting blood-sugar determinations in this series of thirty-six cases of typical eczema, as contrasted with McGlasson's series of 158 cases of miscellaneous disorders, mostly of an eczematous type. In McGlasson's series, 87.9 per cent gave fasting blood-sugar values of 120 mgs. or more per 100 cc. of blood, in contrast with only 8.3 per cent in this series. It is possible that the study of more cases will raise the average fasting values.

A detailed study of the tolerance curves, however, confirms the impression given by McGlasson's work: namely, many cases of eczema are associated with a disturbance of carbohydrate metabolism. As a basis for comparison of these glucose tolerance reactions in eczema, a large series of tests in clinically normal individuals, recently reported by Horace Gray, was used. These control determinations were collected from recent literature, and represent results obtained according to various standard technics. Of these normal controls, 276 fasting blood-sugar tests were made—158 at the end of one-half hour, 300 at the end of one hour, 253 at the end of two hours, and 103 at the end of three hours. Of the thirty-six eczema cases, thirty were tested at all five intervals, and six were tested only at the fasting—one hour and two-hour periods.

Figure 1 illustrates the sharp contrast between the average curve of the thirty patients who were tested at all five periods, and the average curve of the clinically normal controls. If the six eczema cases who were not tested at the one-half and three-hour periods were included, the contrast would be even more marked, because the average value of these six patients at the end of the first hour was 240.8 mgs. per 100 cc. The one-half-hour period probably would have shown an even higher reading.

Some of the curves in patients with typical eczema coincided with the average normal. Many of the curves showed values of 200 or more even at the end of the second hour, the normal being 105 (Gray's series). The patient showing the greatest abnormality was a man 21 years old who had a papular eczema of the face, neck, and arms of three months' duration. His fasting blood sugar was 219.7, at one-half hour it was 235.5, at one hour 317.4, at two hours 303, at three hours 200. In this case the urine was negative for sugar throughout, although many of the eczema cases showed glycosuria at the first, second, or third hour. One patient who had what was supposed to be an occupational

FIGURE 1. Average curve of thirty eczema cases which were tested at all five periods (upper line) in contrast with average curve of normal cases.

eczema of the hands from soap and water showed 0.9 per cent of sugar in the urine at both the one and two-hour periods, and a blood sugar of 108 fasting, 296 at one hour, and 182 at two hours. Although he made very little progress under local treatment alone, the condition entirely cleared up when he was placed on a low carbohydrate diet.

Of the thirty cases tested at all five periods, the peak of the curve was reached at the one-half-hour period in 53 per cent, at the one-hour period in 36.6 per cent, and at the two-hour-period in 6.6 per cent. Thus, there is a tendency not only to develop a higher peak in eczema, but a delayed rise and also a delayed return to normal. Of these thirty cases which were tested at the three-hour period, only 56 per cent had returned to 100 mgs. or below, the average of the controls being 93.9 mgs.

The high percentage of cases in the entire series of thirty-six eczema cases showing unusually high values at the one and two-hour periods is shown in Figure 2. The fact that 16.6 per cent of the eczema series showed values of 200 or more at the end of two hours, while only 0.8 per cent of the control series showed such value, is one of the most striking evidences of a disturbance in the carbohydrate metabolism in at least some cases of eczema.

The interpretation of these findings must be approached with the utmost caution, since the series is not large enough to permit sweeping deductions. Nor has the investigation been under way long enough to permit adequate observation of the therapeutic benefits resulting from a low carbohydrate diet. In a few instances where the patients have remained under observation the results have been highly gratifying; this accords with McGlasson's observations. Repetition of the tests following a period of low carbohydrate diet would be of value in determining the ability of the patient to recover his tolerance for sugar. Whether the decreased carbohydrate tolerance, which occurs in many cases of eczema, is due to some underlying endocrine disturbance or to functional overstrain of the pancreas

from excessive carbohydrate intake is a question for further investigation to decide. A history of an excessive use of sugar or starch is not always obtainable.

It must be emphasized that some cases of typical eczema show perfectly normal sugar tolerance curves. It must be clearly understood that a decreased sugar tolerance is not being urged as the cause of eczema. Subsequent investigation may show that the decreased tolerance per se is the cause of some cases of eczema, and that it is only an incidental symptom of some more fundamental cause in other cases. Protein sensitization is still an important factor to be reckoned with in many cases of eczema, especially in infants. One patient in this series, a boy 12 years old, showed a definitely decreased tolerance, and also gave strongly positive cutaneous reactions to five of the common food allergens among the grains, fruits, and vegetables. Another patient, a man aged 34, gave strongly positive reactions to several pollen and vegetable allergens, but showed a normal sugar tolerance curve.

SUMMARY

1. A preliminary report is presented, dealing with the glucose tolerance reactions in a series of thirty-six consecutive cases of typical eczema.
2. The tests were made in two laboratories, each using the Folin-Wu colorimetric technic.
3. The fasting blood-sugar values in these cases of eczema were not found to be abnormally high, except in a few cases.
4. Very striking deviations from normal were found, however, at the one and two-hour periods, following the administration of the test glucose solution. Of the thirty-six eczema cases, 33.3 per cent showed 200 mgs. or more of glucose per 100 cc. of blood at the end of one hour, in contrast with only 5.6 per cent of 300 normal controls; and 16.6 per cent of the eczema cases showed 200 mgs. or

FIGURE 2. Percentage of abnormal readings.

	FASTING	1 HOUR	2 HOURS
Mgs. per 100 cc.	Per cent of cases	Per cent of cases	Per cent of cases
	120 or above	200 or above	200 or above
NORMAL	7.9%	5.6%	0.8%
	276 cases	300 cases	253 cases
ECZEMA	8.3%	33.6%	16.6%
	36 cases	36 cases	36 cases

more at the end of two hours, in contrast with only 0.8 per cent of 253 normal controls.

5. Of the thirty cases which were tested at the end of three hours, 40 per cent had not returned to a conservative estimate of normal (100 mgs.).

DISCUSSION

OSCAR V. SCHROETER, M. D. (1002 Union Bank Building, Los Angeles)—Ayres' paper serves to accentuate the conclusion that eczema is only what dermatology and etiology prove it to be, a varying symptomatic manifestation; it is a cutaneous reaction. This reaction has, undoubtedly, a varying basis, due to the different pathologico-chemical state of the blood in different diseases and also to the particular degree of tolerance in various individuals to the same. This latter factor, only, can account for cases of poor sugar tolerance, which show no dermatological reaction. But the answer to the question, "Why does one individual with poor sugar tolerance have eczema and the other not?" is a deeper and more difficult problem of greater value. Various chronic diseases and disorders of metabolism produce eczema. Doctor Ayres has, very accurately, shown one. The therapeutic problem of dermatologists, in the face of an eczema, is to learn the particular basis of the same and treat it, as well as the skin condition locally.

KENDAL P. FROST, M. D. (Pacific Mutual Building, Los Angeles)—We are indebted to Doctor Ayres for elaboration on McGlasson's primary work in this field. I believe that the sugar level is not the only way in which these patients show themselves chemically. I feel that many patients who fall in this group are not entirely expressed in terms of carbohydrate, but that there is a protein element as well. This has been shown by Lorena M. Breed of Pasadena, whose results were published in a large series of cases not primary eczemas, but many of her cases had both disordered protein and carbohydrate metabolism of a type which seemed to point to liver disturbance. This group has recently been brought to our notice and promises to become an important one.

The picture of eczema and dermatitis is so complex that we are always grateful to anyone who is able to throw more light on the subject. Personally, I prefer to follow the French terminology and speak of "the eczemas" rather than in the singular term "eczema."

LORENA M. BREED, M. D. (Pasadena Hospital, Pasadena)—Doctor Ayres has emphasized one constituent only of the blood, blood sugar, in his study of eczema. It might be interesting, and instructive as well, to study the complete blood chemistry in these cases, and also to ascertain in what classes of cases one finds an elevation of fasting blood sugar.

In his work on protein therapy and the non-specific reactions, Petersen reports a constant elevation of blood sugar during the period of anaphylaxis.

The fasting blood sugar is very often elevated in people with a normal sugar tolerance because of a slight acidosis during even the short fasting period between the evening meal and breakfast. In these cases a carbohydrate meal or a dose of glucose will relieve the slight acidosis and the sugar level will return to normal. We often find, during a glucose-tolerance test, a fasting blood sugar level of 200 mgs. or over, and one hour after the per body weight dose of glucose, that it is lowered to 100 mg., instead of being elevated.

Fasting blood sugar is almost always high in lowered liver function, especially in cholecystitis. Only last week

we were called upon to do a blood chemistry for a patient who was awaiting an operation for gall-bladder disease. The blood sugar was 250 mgs. and the surgeon hesitated. After two days on a pureed vegetable diet, the blood sugar was 240 mgs. and the operation was performed. The gall-bladder was thickened and contained stones.

In a study of 250 cases on whom functional tests were done, together with complete blood chemistry on each, high values for blood sugar and uric acid, as well as N. P. N., were constantly found in those cases with clinical evidence of cholecystitis. Of this number twenty were operated and we had the opportunity of seeing, not only the pathological gall-bladders, but that the blood sugar and uric acid returned to normal following the operation.

That an absorption of split-proteins, whether from the intestinal tract, or from some focus of infection, will produce a sensitization of body cells is a well known fact. When we remember that the liver is very closely associated with the perfect digestion of proteins, that it stores sugar, and that one of its most important functions is that of detoxication, it becomes evident that this organ and its various functions must be reckoned with in any case of protein-sensitization, whether manifested on the skin, as in the eczemas, or on the mucous membrane of the respiratory tract. As the histology of the skin and the mucous membrane is the same, we may have eczema in one person, hay-fever in another and asthma in still another, or all three affections in the same person from the same cause.

GEORGE PINESS, M. D. (1136 West Sixth Street, Los Angeles)—From observation of Ayres' charts, I am inclined to believe that most of the cases presented here have an endocrine disturbance associated with their eczema, either having a definite relationship toward eczema or by being simply coincidental. I feel that if the series of patients studied by Ayres were tested to proteins, and by that I mean just at the proper time with properly prepared proteins, a great many of them would give definite reactions. It is an accepted fact that eczema is an allergic reaction and, as shown by the work of Petersen, blood sugars are constantly elevated during anaphylactic periods. Therefore, I contend that probably the cases discussed by the writer are of protein sensitive type and that the blood sugar tolerance tests are not an etiological factor.

H. P. JACOBSON, M. D. (424 South Broadway, Los Angeles)—Doctor Ayres' venture into the study of relationships between eczema and metabolism will serve a two-fold purpose of emphasizing anew the futility of attempting to treat these cases purely as local conditions, and will, no doubt, serve to stimulate others to further study of the problem from the standpoint of etiology.

His observation of an impaired glucose tolerance in patients suffering from eczema represents only one factor in a complex problem, the solution of which is, as yet, incomplete. It is my impression that the abnormal glucose curve in these patients is significant of a type of alimentary hyper-glycemia due to a hepatic deficiency and an inability on the part of the liver to convert glucose into glycogen in normal quantities. These patients almost invariably complain of a chain of digestive symptoms referable to the gastro-hepatic tract, thus lending weight to the presumption that the reason for the abnormal glucose curve in the blood is to be found in the liver.

The nature of the particular hepatic lesion in any given case, of course, varies. In some, it may simply consist of an exhaustion of the organ, brought about by an over-indulgence of carbohydrates and thereby overtaxing the functional capacity of the liver. In others the exhaustive state may be brought about by a focal infection in some remote part of the body or in the immediate neighborhood of the gall tract, surcharging the portal circulation with bacterial toxins and thereby making a consequent extra heavy demand upon the liver and upon its detoxicating function. (The liver is one of the chief detoxicating organs in the economy.) Or, as a result of a generalized degenerative process in the vascular, cardiac or renal system, the liver becomes involved, in which event, not only will there be found an impaired glucose

curve, but the values of the products of the protein metabolism generally will be found altered.

In other words, the fairly constant impaired glucose curve, observed in cases of eczema by Doctor Ayres, should be interpreted in the light of a symptom only, the cause of which must be sought for in every case to enable us to proceed with judicious treatment. That, in turn, implies a comprehensive knowledge of, and skill in, the theory and practice of internal medicine.

DOCTOR AYRES (closing)—I appreciate very much the generous remarks and the valuable suggestions which have been offered in the foregoing discussions. I have merely tried to call attention to the role of the carbohydrates in the problem of eczema.

Carbohydrate metabolism, on the other hand, is intimately linked with other vital functions upon which detailed observation and research must be focussed before the riddle can be solved.

With all due respect to the splendid work which Piness has done in the field of allergic phenomena, I cannot subscribe unreservedly to his statement that "it is an accepted fact that eczema is an allergic reaction."

Some eczemas are allergic reactions, just as some headaches may be allergic reactions, but it would be inadvisable to admit of no other causes. The eczemas on the hands of dishwashers and the eczemas due to various other external irritants are certainly not of the protein sensitive type. On the other hand it would seem quite reasonable that there may be an associated disturbance of both protein and carbohydrate metabolism in some of the eczemas. I would be the last to say that many of my cases did not fall in this category. But, again, I do not believe it has been proved that protein sensitization is an ultimate cause. Certain facts point to allergic reactions as symptoms of more fundamental disturbances, just as in the case of decreased carbohydrate tolerance, and the real solution of the problem lies in the discovery and correction of that primary disorder. Breed's observation on liver function seem to me to offer extremely interesting possibilities.

Again let me emphasize the fact that I am not urging carbohydrate intolerance as the cause of all eczemas; it is only a small but very important factor.

Oxygen Want in Health and Disease—Charles W. Greene, Columbia, Mo. (Journal A. M. A.), discusses the oxygen capacity of the blood; normal alveolar oxygen pressures; the physiology of high alveolar oxygen pressures; the physiology of low alveolar oxygen pressures; the anoxemic crisis; the significance and danger of the asphyxial post-crisis events; the remedy for anoxemia—an artificial oxygen supply; oxygen want in anesthesia; oxygen availability in disease; the oxygen problem in cardiac deficits, and the anemias. He concludes that the administration of oxygen has no advantage to the normal body. Airs of more than 60 per cent of oxygen may produce pulmonary inflammation by local action. Oxygen administration has no physiologic clinical advantage in hemorrhage, anemia, or other circulatory mechanical defects. Oxygen-enriched airs are of life-saving value in all clinical cases of pulmonary obstruction, edemas or other deficiencies that retard the process of oxygen absorption or prevent the full saturation of the hemoglobin of the pulmonary blood. Oxygen administration must be controlled by recognized physiologic methods, must be continual, and must not produce local pulmonary injury. Oxygen administration cannot be successfully pursued except with clear understanding of the type of response to anoxemia and the recoveries on re-oxygenation through the complex and interdependent reactions of the nervous system, the respiratory system, the circulatory system, and the blood. For all these we have in present-day methods and animal verification an accurate scientific basis of determination.

THE USE OF WHOLE LACTIC ACID MILK IN PRIVATE PRACTICE

By JAMES W. CHAPMAN, M. D., Pasadena

Lactic acid milk changes the bacterial flora of the intestine only to a slight extent and this change is not essential for its beneficial action.

Milk, soured by addition of U. S. P. Lactic Acid in the proper amount, seems to have an effect practically the same as that soured by organisms.

The chief advantage of whole lactic acid milk lies in the fact that it is a concentrated food and can be fed to athreptic infants and other below-weight infants, whose tolerance for fat and sugar has been lowered, in sufficient amounts to bring about a gain without causing an intestinal disturbance.

Whole lactic acid milk is not a panacea. I do not believe its use is indicated in normal infants. We have found it to be of greatest value in the feeding of the so-called athreptic infant, although, in some intestinal upsets, its value is unquestioned.

DISCUSSION by T. C. McCleave, Oakland; Paul S. Barrett, Fresno.

NO NEW facts are presented in this paper. It was written because we thought it might be of more or less general interest to relate some experiences with the use of whole lactic acid milk in private practice, where conditions are vastly different from those found in hospitals and institutions where most of the work with soured milk formulae has been done.

At the outset it might be of some interest to describe briefly the historical background of soured milk and its use as an article of diet. It has been used extensively among all peoples and in all climes for untold centuries. As a food for infants and invalids it has been used by the Armenians and other Near Eastern peoples quite as long as the well-known matzoon.

Metchnikoff attributed the sturdy health and longevity of certain of the Balkan peoples to their extensive use of soured milk as food. His observations and investigations gave a tremendous impetus to the use of soured milk and to the souring agency, the so-called *B. bulgaricus*. Metchnikoff attributed the beneficial result following the use of sour milk to the organisms souring the milk, stating that they brought about a change in the bacterial flora of the intestine. For many years soured milk and the various organisms capable of souring milk were given for no other purpose than to bring about a change in the bacterial flora of the intestine. Beneficial results were explained on such a basis. First, *B. bulgaricus* held the limelight and Bulgarian tablets were prescribed at the least provocation; later, *B. lactic acid* and *B. acidophilus* became the organisms of choice for one reason or another, based on not very convincing experimental work.

That there seemed at first glance very good reason to suspect intestinal bacteria of causing many of the diarrheas of infancy and childhood, may be seen when stools are examined during an intestinal upset. Often pure cultures of one organism are found, the commonest perhaps being *B. coli*, *B. welchii*, *streptococcus faecalis*, *B. pyococcyaneus*, and *B. proteus*, and to each one at some time or other has been ascribed the causation of diarrheas in infants.

The result of most of the work done in recent years on the subject of the role of bacteria in the

etiology of diarrheas in infancy, excluding, of course, the dysentery group, has been, I believe, overwhelmingly against the opinion that they have much to do with it. Their presence in more or less pure culture seems to be rather an effect than a cause. The intestinal mucosa, damaged by too much or improper food, seems to be unable to exert its normal inhibitory power over the growth of these organisms.

Veeder some years ago worked on the problem, and his conclusions were that bacteria had very little to do with the vast majority of diarrheas and intestinal upsets occurring in infancy. Howland and Marriott seemed to hold the same views. The work of Davison and Rosenthal seems also to belittle the role of bacteria in causation of diarrheas in infancy. A report of work done by investigators in various parts of England on the bacteriology of normal and diarrheal stools in children is perhaps most convincing. These investigators were unable to find evidence that bacteria usually found in normal intestines are ever the cause of diarrheas in infancy and childhood. It would seem, therefore, that we must conclude that, while it is conceivable that the bacterial flora of the intestine might play a part in the etiology of diarrheas in infancy and childhood, it has never been proved that they do.

If bacteria have nothing to do with the etiology of the majority of the diarrheas of infancy and childhood, we must discard Metchnikoff's theory and look about for some other explanation for the beneficial results following the use of soured milk. In 1902 the *Jahr buch für Kinderheilkunde* carried a report of the use of acidified milk in infant-feeding. In 1909 M. Klotz, in the same journal, reported that acidified milk had a favorable effect on fat protein and mineral absorption. We do not see reports in the literature of acidified milk being used again in infant-feeding until 1918, when Marriott called attention to its advantages.

Marriott was engaged at the time in investigating the reasons why an infant's tolerance for cow's milk was less than for woman's milk. He concluded that the reason was that the cow's milk was so much richer in buffer substances. These buffer substances required so much acid to neutralize them that the acidity of the gastric juice was lowered to a point where it did not properly function. He thought that if cow's milk were acidified, much more could be given at a time without causing a gastro-intestinal upset, because the buffer substances would be to some extent rendered inert before entering the stomach, and the acidity of the gastric juice would not be changed to any great extent.

The initial process of digestion in the infant's stomach depends on the HCl secreted by the gastric glands. Normally, the amount secreted is optimum for the digestion of breast milk. Breast milk, compared with cow's milk, is highly acid, that is, it has a comparatively high P_h index—about three times as high as cow's milk. Theoretically, at least acidifying cow's milk, with an amount of acid that would bring the P_h index up near that of breast milk, would be a great aid to the digestion and assimilation of cow's milk.

With these ideas as his guiding principles, Marriott began working with cow's milk, soured by incubating in it a pure culture of *B lactic acid* aero-

genes. To make up the difference in the carbohydrate content between cow's milk and breast milk and so increase caloric value, cane sugar or the dextri maltose was used. Later, karo was used almost exclusively. Karo syrup was used for the reason that, being a mixture of several sugars, it should be ideal for the purpose, containing, as it does, dextrin 55 per cent, maltose 30 per cent, and glucose 15 per cent. The readily absorbed and difficultly fermentable dextrin and glucose is nicely balanced against the easily fermentable maltose, making a mixture that is not conducive to diarrhea; in fact, surprisingly large amounts may be given without getting into difficulty.

The Mixture Described—Cow's milk, soured by incubating in it bacteria and an easily assimilable carbohydrate, has a P_h index very nearly approaching that of breast milk and a caloric value per ounce equal to that of breast milk. The results obtained from the use of the mixture in the St. Louis Children's Hospital and the Washington University showed very conclusively that it was of great value, if not in all feeding cases, certainly in those most difficult of all the athreptic type.

After leaving the hospital and attempting to use cow's milk soured bacterially, all manner of difficulties were encountered. The question of which bacteria to use in souring the milk was a big one. Contamination and death of the cultures, through lack of proper facilities for handling, occurred frequently. The age, purity and viability of commercial cultures varied, and consequent variations in acidity resulted. Often the expense of cultures or of milk soured commercially was an item to be considered. In many homes the cultures could not be handled properly, the question of temperature and contamination being too much for the average mother. The acidity of the milk was never above suspicion. It seemed to me that unless the acidity of the milk is more or less constant, much of its benefit is lost. Frequently enough to keep up our interest, milk could be soured in the home under conditions which made it dependable, and in these instances the results were uniformly good. On the whole, however, the use of milk soured bacterially outside hospitals seemed to me very unsatisfactory. Influenced by others who claimed to have obtained good results from their use, alleged pure cultures of bacteria in various forms—liquid, jelly, and tablets—were used, but no good results were obtained that could be attributed to the cultures. As a matter of fact, none could be expected from their use because acid must be present in cow's milk prior to introduction into the infant's stomach if we expect to reduce the content of buffer substances in cow's milk and so protect the acidity of the gastric juice.

The acid content of milk soured in commercial laboratories is rarely ever above suspicion. It is, of course, possible to obtain milk soured in commercial laboratories, but so far we have no evidence that convinces us that they can be used to accomplish our purpose. One seldom finds in such laboratories workers who really get the clinician's point of view. Most of them stress the point that their product changes the bacterial flora in the intestine, but, as has been pointed out, we do not believe this

to be of much importance in dealing with intestinal upsets of children. Bacterially, soured milk will vary in acidity between wide limits according to the bacteria used. To produce a milk soured bacterially, in which the acidity is proper and constant day after day, requires a scrupulous attention to detail, which is beyond most commercial laboratories. Most of the commercial soured milk has an exceedingly sour taste which often results in the infant's refusing to take the milk, and in some instances this has been known to prejudice a certain type of mother against the milk, which naturally complicates matters.

In the face of such difficulties, we came to the conclusion that lactic acid milk, as produced by incubating in it certain bacteria, could not be used as extensively as it should in private practice. Some diarrheas could be controlled with protein milk, and the infant could be made to gain for a time by adding carbohydrate and a little fat, but this scheme had its limitations and we were soon forced back to a sweet milk formula. In certain types of cases as soon as a sweet milk formula was given, a stationary weight resulted, and if then enough carbohydrates and fat were added to bring about a gain in weight, greasy stools returned.

The so-called athreptic infants presented, and for that matter do now present, the greatest problem. All pediatricists are only too familiar with the infant who will not gain unless given an amount of food which, even if continued a short time, will bring about an intestinal upset. An infant, in other words, who requires more food in order to gain weight than it can assimilate without going beyond the limits of its tolerance. We felt that if these infants could be given whole lactic acid milk, they would all gain weight and their tolerance to fat and sugar could be increased.

It was suggested to me by J. F. Perkins of Dallas, Texas, who, under Marriott at St. Louis, had been a pioneer in the use of whole lactic acid milk, that U. S. P. lactic acid could be added to sweet milk and used exactly as bacterially soured lactic acid milk was used. This idea came to him from Marriott, who, as a result of some work on the acidity of the contents of an infant's stomach, came to the conclusion that the acid was the important factor in sour milk—not the souring agents.

In the choice of an acid to use in souring milk, Marriott was governed by several considerations. Hydrochloric acid, since it is already present in the stomach and is the very acid we wish to protect by acidifying the milk, suggested itself first. It is, however, an inorganic acid and must be neutralized and excreted and might in time become a burden to the body—might even result in acidosis by depleting the body bases. Other organic acids, such as acetic, citric, and butyric, tend to cause diarrhea. Lactic acid seemed most free from disadvantages. Several of the acids named have been used by other investigators, namely, hydrochloric acid by Faber, and citric acid by Hess, and their reports have been favorable, and it may well be that further investigation may show them to be the acids of choice. In the light of the evidence we now have, we believe that lactic acid is the safest, being completely oxidized, requiring no neutralization in the

body, and in the amount necessary to raise the P_h index of cow's milk to the proper point, exerting no harmful effect on the gastric intestinal tract.

The method of souring milk with U. S. P. lactic acid follows very closely that suggested by Marriott. If certified milk is used, no sterilization is deemed necessary, but if ordinary raw milk is used it is boiled five minutes. While boiling, the milk is stirred to prevent the formation of a scum. If such a scum does form, it is removed before the acid is added. After boiling, the milk is allowed to cool, because if acid is added while milk is too warm it will clot in large curds, which will interfere with its passage through the nipple.

U. S. P. lactic acid is used 4 cc. to each 500 cc. of milk, or approximately sixty drops to each pint. The acid is added slowly, one drop at a time, with a medicine dropper. While the acid is being added, the milk should be stirred gently. It is important that the milk be cool, that the acid be added slowly, and that the milk be stirred while adding acid, otherwise large curds will appear. Such curds do not render the milk unfit for use, but they do clog the nipple holes. Vigorous shaking will usually break them up.

If properly made, the mixture should be smooth and homogeneous, and should have the taste and odor of ordinary buttermilk. The exceedingly sour taste of most bacterially soured milk is absent. The P_h index is about that of breast milk, $P_h 4$. Carbohydrate is added to suit the needs of the individual infant—usually about 2 or 3 per cent. Karo corn syrup, dextri maltose, and cane sugar have been used—the two first named most frequently and about equally; the latter only when the others seemed not to be well tolerated. Milk sugar is never used because, not having a sweet taste, the sourness of the milk is not decreased, and also because it probably is not assimilated to the degree that the other sugars named are. The amounts of carbohydrates varied, of course, with the individual's needs and tolerance. In some infants badly undernourished, surprisingly large amounts may be given without harmful results. As a rule, however, we rarely give as much as the usual 3 per cent, finding usually that a satisfactory gain can be brought about with a small amount of sugar. The sugar is always dissolved in warm water before it is mixed with the milk; this facilitates mixing. If the infant is taking cereal, very little or no other carbohydrate is given unless the infant is badly undernourished.

All directions for preparation of lactic acid milk are written in detail, and we convince ourselves that the mother or nurse understands the reason why the acid is added before any attempt is made to prepare the formulae. Usually the lactic acid is not diluted, for the reason that the amount the infant would ordinarily take does not seem to be in excess of his ability to digest it. Never more than a quart is given in twenty-four hours. We believe that if more calories than are represented by one quart of milk, with additional carbohydrates, are required to bring about a gain, other food in the shape of cereals, soups, etc., are indicated.

It is not to be understood that whole lactic acid milk is used wherever and whenever lactic acid milk seems to be indicated. In severe diarrheas or

in cases where infants seem to have had their tolerance for fat or carbohydrate greatly decreased, skimmed milk with no suger added is used—the fat and carbohydrate being added as conditions permit. In such cases where there seems to be an unusually low tolerance for carbohydrate, corn starch is often used, as it seems to be more easily borne than other forms of carbohydrate; usually a 3 per cent solution is used, although we have used it up to 6 per cent, which is rather thick.

It has been our experience that no infant will for long refuse lactic acid milk. Often it is refused at first, but if persistently offered it will be taken quite as eagerly as any other food. A certain type of mother, familiar to all, often is greatly alarmed at the infant's refusal to take the milk, but after being assured, sometimes repeatedly, that the baby will finally take the food, she goes on with it.

We have given lactic acid milk, with few exceptions, to abnormal feeding cases only; that is, to infants suffering from acute or chronic gastro-intestinal disturbances. It has always seemed to me that the simpler a formula could be made, the better for everyone concerned—the infant, the mother or nurse, and the pediatrician; infants showing a steady satisfactory gain on a sweet milk formula are left alone. As a matter of fact, we have noted in several instances where normal infants were given lactic acid milk colic was more frequent than when sweet milk formulae were given, the colic usually being relieved when a change to sweet milk was made. It may well be that the colic was due to some other factor or factors other than lactic acid. We have not sufficient data to say positively; the above is an impression only.

After acute intestinal upsets in which protein milk has been used, in changing from protein milk to sweet milk, a lactic acid formula is valuable. We have had less trouble when it has been used between protein milk and sweet milk than when the change was attempted without it. In some cases, where it seemed indicated, we have used a formula suggested by John Howland and called by him "Reinforced Protein Milk," which is made by adding the curd from a quart of sweet milk to a quart of lactic acid milk made from skimmed milk. With his formula, carbohydrates are necessary—if not at first, at least within a few days, if a weight loss is to be avoided.

Lactic acid milk, made by souring whole milk or skimmed milk with U. S. P. lactic acid, has been used by us in approximately 50 per cent of the abnormal feeding cases seen in the past year. A number of normal infants were given lactic acid milk; some were fed lactic acid milk, so that we might use them as controls; others because lactic acid milk seemed safest because of their geographical location, lack of facilities for cooling milk, and for other like reasons. In a few of the normal infants fed lactic acid milk, colic, or what seemed from the descriptions to be colic, developed. In no case was it accompanied by a gastro-intestinal upset, and in every case a return to a sweet milk formula stopped the symptoms promptly. We have considered here only the cases in which lactic acid milk seemed definitely indicated. These number fifty-one. Thirty-two are from our private practice, and nineteen are from

two clinics. The cases from the clinics were included because the milk in every case was prepared at home with no personal supervision. A number of other infants were given lactic acid milk, but they are not included because they were seen so few times or so irregularly that the results have no meaning. In only one instance do we know definitely that a diarrhea developed while lactic acid milk was being given, and in this case, in our absence, the infant came under the care of another pediatricist who changed the formula.

	No.	Average Age	Average length of time on W. L. A. M.	Average Weekly Gain
Private cases.....	32	5½ mos.	42 days	8¼ oz.
Clinic cases	19	4 mos.	45 days	7½ oz.

Two cases are described in detail:

CASE 1. Baby L.; age 3½ months. Birth weight, 7¼ pounds; breast fed, two months; then Eagle Brand for two weeks; stools became loose, green with mucus and curds; changed to Mellin's Food; stools improved but did not gain. One month ago changed to cow's milk formula but has not gained; each time formula strengthened an intestinal upset followed; now at 4½ months the weight is 9⅞ pounds; has three or four greenish, yellow stools a day which contain mucus and protein curds. Because of the clear evidence of lowered tolerance for fat and sugar, skimmed milk acidified and diluted with plain boiled water was given. The first week no gain was recorded, but neither was there a loss; the stools improved, became yellow, smooth and pasty, whereupon whole milk was used but no carbohydrates. The next report, made one week later, showed a gain of 6 ounces. One per cent carbohydrate in the form of Karo was added and the next week a gain of 13 ounces was recorded. The next week the mother reported baby constipated. Carbohydrate was increased to 3 per cent and prune juice was advised. April 3 the weight was 10 pounds 8 ounces. Approximately one month later, May 1, the weight was 13 pounds. June 5, the weight was 15 pounds 5 ounces; July 10, the weight was 16½ pounds. The baby at this time was 7 months old. Lactic acid was discontinued and a diluted sweet milk formula given with soups and cereal. No intestinal disturbances were recorded after lactic acid milk was given except the light tendency toward constipation at first, which was overcome by more carbohydrate and prune juice. At one year the baby weighed 20 pounds 15 ounces, and measured twenty-nine inches in length.

CASE 2. Baby K. B. S.; age 4½ months. Birth weight, 8 pounds 1½ ounces; present weight, 10 pounds 6 ounces; was on breast for one month; did well; changed to four-hour schedule and then weaned in a short time because milk supply seemed to be failing; since has lost weight. Has been on Mellin's Food, Eagle Brand, Mrs. Alberty's food and modified cow's milk formula; did not improve on any; constipated since he has been on cow's milk; before on proprietary foods stools always watery, green; cried a great deal. Examination revealed nothing of importance except very thin, emaciated infant and certain degree of anhydremia-turgor being slightly reduced. Put on W. L. A. M. formula of 32 ounces: Six and one-half ounces five times a day, 3 per cent carbohydrate. In week following, infant gained 12 ounces; in next two weeks gained 27 ounces. In the 2½ months he remained on the lactic acid formula he gained a total of 5 pounds 9 ounces. Lactic acid was discontinued and the baby put on sweet milk formula with cereal gruel and soup. At 8½ months his weight was 19 pounds 6 ounces.

These two cases are typical. Other cases might be detailed in which most astounding gains appear. In one which occurs to us there was a gain of 18 ounces in one week and with no evidence of nutri-

tional edema and no intestinal disturbance, but such cases are not as typical as the two detailed are.

SUMMARY

1. Lactic acid used in infant-feeding seems to make its first appearance in the literature in 1902. In 1904 another report appears in which it was claimed that the addition of lactic acid to the food of infants resulted in distinctly better assimilation of all food elements from the gastro-intestinal tract.

2. Marriott, in 1918, after working with cow's milk in which lactic acid-producing organisms had been incubated, came to the conclusion that the acid, by removing the excess of buffer substances in cow's milk, rendered it easier of digestion.

3. Lactic acid milk changes the bacterial flora of the intestine only to a slight extent, and this change is not essential for its beneficial action.

It is almost impossible to successfully use bacterially soured milk in private practice except in a few cases in which conditions were exactly favorable. Milk soured by addition of U. S. P. lactic acid in the proper amount seems to have an effect practically the same as that soured by organisms. Lactic acid seems preferable to HCl and other inorganic acids, for the reason that it does not require neutralization in the body and can be almost completely oxidized in the body. There is the danger in the use of inorganic acids that they might, if used over a long period of time, deplete the bases of the body to the extent that an acidosis results.

The chief advantage of whole lactic acid milk lies in the fact that it is a concentrated food and can be fed to athreptic infants and other below-weight infants whose tolerance for fat and sugar has been lowered in sufficient amounts to bring about a gain without causing an intestinal disturbance.

Whole lactic acid milk is not a panacea. I do not believe its use is indicated in normal infants. We have found it to be of greatest value in the feeding of the so-called athreptic infant, although in some intestinal upsets its value is unquestioned.

DISCUSSION

T. C. McCLEAVE, M. D. (Medical Building, Oakland)—Sour milk preparations are very widely used in the dietary of many different peoples and have had ascribed to them, by certain medical writers, nutritive properties not found in fresh milks. The Metchnikoff propaganda for soured milks attracted general attention because of his authoritative position as a bacteriologist, although his views on the subject were soon shown to be extravagant.

He believed the beneficial effect of soured milks to be due to the contained *B. bulgaricus*, and, as the sour taste is objectionable to many persons, pure cultures of this organism were often given, instead of the milk, in digestive disturbances considered suitable for treatment by this means. Later, *B. acidophilus* became the popular organism, largely displacing *B. bulgaricus*.

As stated in the paper, however, the work of Howland and Marriott and their associates appeared to show that the presence of any particular organisms in the digestive tract was not the important factor, but that to the high lactic acid content of the milk was due the benefits which, undeniably, follow its use in certain dyspepsias of infants and young children at least, and the difficulties encountered in the preparation of soured milks, by the addition of bacterial cultures, have been obviated

by the simple addition of suitable amounts of lactic acid, or, less commonly used, hydrochloric acid.

There can be no question that milk thus acidified is very valuable in certain feeding cases which do badly on ordinary milks. The taste is objectionable, however, and mothers are loth to feed it, but, fortunately, although cow's milk is rich in buffer substances, most healthy babies can digest it perfectly well when suitably modified and boiled, and acid milks are not generally necessary.

PAUL S. BARRETT, M. D. (Bank of Italy Building, Fresno, California)—For a considerable period of time the technical difficulties in the preparation of fermented or acid milk formulæ made them suitable only for use in institutions. With the change to the simple addition of lactic acid, however, the home preparation no longer presents a difficulty, providing the instructions are followed. It is my custom to boil all milk used and instruct the mother not to add the lactic acid until the milk is thoroughly cooled. Then, by adding the lactic acid drop by drop, stirring with a glass rod, a smooth, non-curdled mixture is obtained. It is also important not to heat the food above 100 degrees F. before a feeding, in order to avoid curdling.

Occasionally, in feeding a mixture according to Marriott's formula of a dram to a pint, the mother reports that the child vomits after every feeding. It is often advisable to decrease the acid content for a few days and then gradually increase it again.

It has been generally proven that lactic acid facilitates the digestion of fats but not the sugars. Experience shows, however, that it is possible to bring the carbohydrate up to a higher per cent than has heretofore been practical.

Recently, I have been using the lemon juice milk as advocated by Hess of New York with similar results; both mixtures, with their added carbohydrate, being perfectly palatable to most infants. The mothers, almost without exception, become interested in the procedure, and, after a few weeks' trial, become enthusiastic over the "sour milk feeding."

Finally, I wish to thank Doctor Chapman for bringing the attention of physicians to a method of feeding, which, while not a panacea, is certainly another valuable addition to the management of the so-called difficult feeder.

DOCTOR CHAPMAN (closing)—It has not been my experience that infants will long refuse milk acidified with U. S. P. lactic acid. Such a difficulty was common with the use of bacterially soured milk. I explain to the mother exactly why the acid is added and what to expect from its use. I have encountered practically none who objected to its use.

It has been shown quite conclusively, I believe, that very often, when an infant's tolerance for fat has been lowered, the tolerance for sugar is lowered to some extent, and, when the tolerance for fat is raised, more carbohydrate may be taken. I do not believe that citric acid will prove to be as satisfactory as lactic acid in infant feeding for the reason that the acidity of lemon juice varies, and danger of a gastro-intestinal upset is greater than in lactic acid milk.

I would like to say, finally, that, while I do not believe that soured milk will displace the simpler formula of cow's milk, water and carbohydrate, I do believe that it has a very definite place in the armamentarium of the physician who feeds infants. It is, perhaps, the most valuable addition to infant feeding since Finkelstein's "Eweiss" milk was introduced. With the proper use of w. l. a. m. and protein milk, there are practically no feeding cases that cannot be successfully handled.

The fact is that, while babies born today have many times more chance of living to maturity than they did twenty-five years ago, the person of 35 today needs help to keep as many years ahead of him as had his grandfather when he was 35 years old. The failure is that of the individual—not of medical science or physicians. Today man has everything but himself working in his favor for health and longevity.—William G. Exton, M. D.

Well, well, old fellow, you look half dead. Why don't you take a vacation, or *have* you?

X-RAY OF THE URINARY TRACT, WITH REPORT OF A CASE OF CONGENITAL UNILATERAL KIDNEY

By FRANCIS B. SHELDON, M. D., Fresno, Calif.

Review of literature.

Technic of combined radiologic and urologic diagnosis discussed.

For literature quoted, see Quarterly Cumulative Index, A. M. A., or Index Medicus.

Frank discussion by George W. Hartman, San Francisco; H. E. Ruggles, San Francisco; Edward N. McKee, Los Angeles; Charles M. Richards, San Jose.

THE manner of examining the urinary tract with the x-ray, may, like ancient Gaul, be divided into three parts. First, films taken without cystoscopy and catheterization of the ureters. Second, films taken after cystoscopy and the catheterizing of the ureters. And third, films taken after an opaque media has been thrown into the kidney cavities and the ureters. This same opaque media injected into the bladder oftentimes will give us useful information.

Good films of the urinary tract should show the outline of the kidney shadow, the border of the psoas muscle, the lower ribs, and the transverse processes of the lumbar vertebrae, and the lower part of the tract, the pelvis must be well shown also. From films made when the ureters have not been catheterized, we are able to get information regarding the position of the kidney in its relation to the surrounding body structures, the size of the kidney, and whether or not there is any opacity casting a shadow suggestive of a calculus. Before such a shadow is diagnosed as being a calculus, the relation of the shadow to the position of the other shadows of the urinary tract must be considered.

With the ureters catheterized, using a catheter that is opaque to the ray, with a single film the relation of any opacity to the urinary tract may be fairly well located. With shifting of the tube between exposures and a double exposure on the same film, or with stereo films, the location may be made more exact. In the case of a shadow of an opacity near the ureter, it must always be borne in mind that the ureter may be very much dilated, and a calculus within the ureter in such a case may not be in contact with the catheter. In these cases a final diagnosis must be made only after a good ureterogram has been made, using an opaque media in the ureter.

The most information regarding the urinary tract is obtained when the entire tract is filled with an opaque solution. The shadow of this opaque solution gives us the size, shape, and position of the various parts of the tract. Various anomalies are found with these films that otherwise would not be known. A kidney may give a good function test and at the same time be discharging much pus. When the roentgenogram is made it is found that there is a double pelvis in the kidney, one of which only is functionless. With two films or a double exposure on the same film after shifting the tube, it is possible to determine strictures of the tract. Pathological changes may take the form of contractions, displacement of the media by new growths, or dilatation of the pelvis, calyx, or ureters.

The dilation of a hydronephrosis may be confined

to a single calyx, or it may include all the calices. It may be that there is only a slight blunting of the calices, seen in the beginning stages, or it may be the terminal stage when the pelvis proper has swallowed up all of the calices. With the double-exposure film the amount of movement of the kidney during respiration is well shown; also the movement with change of posture.

The ureterogram should show dilatation, if present, and kinks or strictures when present. The normal ureter will show peristaltic waves. These latter must not be mistaken for strictures. Here again the two exposures will assist in making the diagnosis. Certainly, a diagnosis of ureteral stricture should not be made from a single film.

Oftentimes the presence of diverticulum of the bladder can be determined only from the cystogram of the filled bladder.

TECHNIC

In private practice I find that most of the patients sent in for urinary tract examination with the roentgen ray are sent with no preparation whatever. When suspicious shadows are found in these cases a recommendation that they see a urologist for cystoscopy is sent, with the report of the findings, to the referring physician. In my own work I do not use compression other than that which I get by having the patient draw in the abdominal wall as much as possible. Double screens at a distance of twenty-one inches from the target are used with high milliamperage and an exposure of one-tenth to one-fifth of a second.

Exposures of the injected kidney are made while the urologist continues to fill the pelvis, for we have found that if the injection is made at about the right rate the return flow is able to care for the overflow, and the peristaltic waves are then seen in the ureters; also the cavity of the kidney is more sure of being full. In our work a 25 per cent solution of sodium bromide is used for the opaque medium. Most always we fill both kidneys for comparison. When the patient complains too much of the discomfort the injection is often stopped, even before the exposure is made. In these cases very often the outlines of the pelvis and calices are not as clear as they should be. I have also noted that the nearer the kidney is to the normal, the more the patient is apt to complain of pain. Some urologists prefer to inject the kidney under the direct observation of the fluoroscope, and then the injection is continued till the solution is seen to flow down the ureter.

Before the kidney is injected a syringe should be attached to the catheter and an attempt made to empty the kidney of any residual urine. This is especially the case where a hydronephrosis is suspected. In many cases where this is not done the pyelogram is not clear because of the dilution of the opaque solution by the retained urine.

CONGENITAL UNILATERAL KIDNEY

The complete absence of one kidney and the accompanying ureter is rather infrequently met. The atrophic kidney with a partial ureter occurs more frequently. L. Polack (1909) collected from the literature 264 cases and analyzed them. He found

the kidney and ureter both absent in 153 of these. Braasch (1912) reports thirty-six anomalies, of which six were complete absence of one kidney. Morris reports unsymmetrical kidney or extreme atrophy of one kidney, occurring once in 2400 bodies. The left kidney is more frequent than the right. He also reports congenital atrophy to the extent of almost obliteration is rare, occurring three times in 15,904 post-mortem examinations.

Thomson Walker (1914) collected ninety-three cases of uremia or anuria, commencing within a few days after operation, and found that in ten cases there was complete absence of the second kidney, and in eight cases there was complete atrophy of the second kidney. A mortality rate of 19 per cent was due to lack of knowledge of the absence of the second kidney. Today, with the use of the cystoscope and the x-ray, such mistakes should not occur.

REPORT OF A CASE

G. L. Single. Female. Age, 22. Weight, about 90 pounds. Came to her physician for lung trouble. The family history was negative. Patient had had measles; petussis, no sequela; diphtheria in 1920. Some edema of the legs followed. Influenza in 1918, but not seriously ill. Tonsils removed in 1920. Menstruation, regular.

At this time (August, 1921) the physical examination was negative, and she was referred by Doctor C. O. Mitchell for a roentgen examination of the chest, which failed to demonstrate any abnormality.

In October, 1923, she was again seen by Mitchell, and at this time her complaint was a pain below the waist line and most severe when sitting. This pain came on suddenly. Two days later the pain was most severe when lying down, and was mostly on the left side. Physical examination showed a temperature of 98 and pulse of 90. Abdomen flat. In the left inguinal region a mass was felt, some two centimeters in diameter, which was freely movable and tender to pressure. On the right was a firm, smooth mass about five centimeters in diameter, freely movable and easily worked up under the costal margin.

In November the patient complained of pain on the right side, and a small mass could be felt. At this time she was referred to me to rule out a possible opaque urinary calculus.

The film showed a very clear outline of the right kidney, which was quite low, the lower pole being but very little above the crest of the ilium. No shadow of the left kidney could be found. A suspected absence of the left kidney was reported. No evidence of calculus was found.

In December the abdominal pain was constant on the right, over McBurney's point; not connected with the kidney, and worse when lying down.

December 15, Doctor W. W. Cross performed a cystoscopy and catheterized the right ureter. No orifice for the left ureter could be found. Under the fluoroscope, when injected with opaque solution, the right kidney was found to move very freely. It would descend till a kink was formed in the ureter, and then could be readily replaced in its normal position. No shadow of the left kidney could be found on the film at this examination.

The patient was later operated. The right kidney was suspended, and the appendix removed. At this time an intra-abdominal palpation was made to try to locate a left kidney, but none could be found. The patient made a good recovery, following the operation.

This case is reported because of its infrequent occurrence and because there have been such cases operated and the single kidney removed. It is essential that every kidney case have a thorough cystoscopic and roentgenographic examination before any operative procedure is done on the kidney.

Mattei Building.

DISCUSSION

GEORGE W. HARTMAN, M. D. (999 Sutter Street, San Francisco)—Radiologic examination of the urinary tract can hardly be considered complete without a catheterization of the ureters with opaque catheters. This not only serves to eliminate shadow-casting bodies exterior to the tract, but also indicates bizarre positions of ureters and kidneys.

Thomson Walker has recently called attention to calcified lymph glands causing hematuria by pressure on the ureters. An opaque catheter would be of assistance in eliminating such an error.

Many physicians are opposed to bilateral pyelograms. With extreme care in injecting, we have not had any unfavorable reactions while doing this. There is a decided advantage in being able to investigate and compare both sides at one sitting.

A problem which remains to be solved is the more successful handling by x-ray of permeable stones which do not show on the plate. We have observed a number of these recently, negative radiologically, in which the stones were passed after cystoscopic manipulation.

H. E. RUGGLES, M. D. (Butler Building, San Francisco)—As Sheldon has pointed out, careful, painstaking work and complete co-operation between the urologist and radiologist are absolutely essential in the field of genito-urinary diagnosis. By working together—preferably in a hospital—good team work is developed, time is saved, patient's discomfort lessened, and the possibility of error in diagnosis reduced to a minimum.

The radiographic examination is the only method of demonstrating anomalies of kidneys and ureters with certainty. Double pelvis may be suspected cystoscopically if multiple ureteral orifices are seen, but frequently the ureters unite in the lower portion of their course and the real situation only becomes apparent in the films.

Stones which may be invisible on plain films of the kidney region (comprising 15 to 20 per cent of all stones) are at times revealed by pyelography. They may appear as "holes" in the opaque shadow of the pelvis, or by absorption of the bromide solution become visible after the pelvis is emptied.

EDWARD N. MCKEE, M. D. (Methodist Hospital, Los Angeles)—One of the important things mentioned by the author, and on which we place great importance, is the preliminary preparation of the patient. About 90 per cent of the patients present themselves without any preliminary preparation whatever. This causes an increase in expense to the patient, as well as loss of time, because the necessary preparation consumes two or three days. Our method is to have the patient take a half ounce of powdered licorice compound on the evening of the second day before coming to the laboratory for examination. Besides the powdered licorice compound, the patient takes repeated S. S. enemas the following evening, and a plain enema on the morning that he reports. The regular diet is continued up to the time of the examination, with the omission of breakfast on that day.

In the matter of technic, Sheldon failed to tell us whether or not he was using the Bucky diaphragm in his urological examination. I believe that the Bucky diaphragm is quite universally used in kidney examinations; and the other essential is a fine focus tube. We also use a compression canvas band with a basketball bladder. The patient is instructed to take a deep breath, exhale, and hold for the period of the exposure.

The technic that we employ is, spark gap, 4½ inches; milliamperage, 20; distance approximately 22 inches; and time, 6 to 9 seconds, according to the size of the patient.

By co-operation the radiologist and urologist are able to make pictures of the ureter from the kidney pelvis to its outlet into the bladder. The radiologist gets everything ready for the picture after completion of the pyelography. The urologist injects the ureter gently with a 20 cc. glass syringe, as he withdraws the catheter. The moment the tip of the catheter enters the bladder he notifies the roentgenologist, and the picture is taken.

The result will be a true picture of any intra-ureteral tumors, strictures, or kinks, and an illustration of the exact topography of the ureter. The procedure is of value in ruling out many of the various pelvic conditions.

Kidney or ureteral pathology otherwise invisible is dis-

closed by the distention it produces in the pelvis or ureter by appearing as a light or negative area in the injected fluid.

CHARLES M. RICHARDS, M. D. (Garden City Bank Building, San Jose, Calif.)—The importance placed upon preliminary preparation, by the author and others discussing the paper, is not overdrawn. Technically, excellent films can only be obtained when the alimentary tract is well emptied of both solid and gaseous contents.

Patients referred to me from out of town frequently come with little or no preparation, and I often try to save them a prolonged stay or a return trip by doing the work immediately, but more often than not the work has to be repeated because the intestinal tract, chiefly the colon, is full of gas. This condition not infrequently is caused by the conscientious effort of the referring physician to prepare his patient by the administration of saline cathartics, most commonly magnesium sulphate. The best cathartics are the vegetable cathartics, castor oil, and licorice powder.

Then, too, an otherwise good preparation has often been spoiled by unskilfully given enemas, whereby large amounts of air have been pumped into the colon; so that frequently we have purposely omitted the enemas, kept the patient on liquid diet for twenty-four hours, and given the vegetable cathartic, thus producing a quite satisfactory preparation.

The report of the congenital absence of one kidney is very interesting, and only serves to remind us that no useful step of preliminary examination can be omitted with safety when nephrectomy is contemplated.

Sheldon's technic of high milliamperage and short exposures is good for the purpose of eliminating respiratory motion, but naturally eliminates the use of the Bucky diaphragm, which is one of my greatest aids in producing valuable soft tissue films, and high contrasts, which may aid in reducing that percentage of undemonstrable urinary calculi.

DOCTOR SHELDON (closing)—It would seem that the use of six to nine seconds' exposure in the making of ureterograms would give an indistinct hazy outline, because of the peristaltic movement of the ureter when filled. This would be similar to taking that much time for an exposure of the stomach. I have, therefore, in my work preferred the rapid exposure technic. I do not see the advantage of long preparation of the patient, if elimination is started two days before the examination and the intestinal tract is at the same time filled by regular diet. The preparation, as given by Richards, is very good.

Hot Air Comfort—Heating methods, heat transmission, comfort, types of furnaces, and ventilation are discussed by Thomas Hubbard, Toledo, Ohio (Journal A. M. A.). He thinks that Americans are becoming progressively more sensitive to temperature and humidity. The popular demand seems to be for higher radiation capacity in the home, in hotels, and in public conveyances. (What a shock it would be to the heating trade if we accepted a 65-degree standard.) Climatic conditions and sudden variations of weather are naturally very trying, and we invite cold shock by hypersensitiveness. Unhygienic heating, combined with foolish estheticism in clothing (e. g., chiffon to furs), results in acute and chronic diseases of the upper and lower respiratory tract. Catarrhal affections, such as chronic sinusitis, even in young children, are far more prevalent than should be tolerated by an enlightened, intelligent people. Medical progress in the study of causes of such diseases is one of the outstanding features of this age, but treatment and cure are handicapped when the unhygienic habit is in itself chronic. The complexion is the color index of good blood and normal skin circulation. It is notorious that in America the natural color index is fading and the cosmetic index is correspondingly high. The skin, like the respiratory mucosa, is actually damaged by hot dry air (and likewise is the hair) and becomes more liable to chronic diseases. Our present high temperature standard so lowers natural resistance to minor and major infections that restoration to normal health is retarded. The fresh air treatment of hospital surgical cases is testimonial to the healing virtue of tonic temperature and natural humidity in convalescence.

AFFECTIVITY—ITS IMPORTANCE IN PRACTICAL MEDICINE

By CHARLES LEWIS ALLEN, M. D., Los Angeles

Affectivity varies enormously in different individuals. Its roots descend to the lowest strata, it dates back to the earliest beginnings of mental life.

Biologically, it stands in close relationship to instincts and temperament.

That differences in affectivity in different individuals depend upon a difference in their make-up, seems pretty certain.

The affective state exerts a profound influence upon the attitude, the expression and the speech, as well as upon the cardio-vascular and glandular systems, and the body nutrition.

Affectivity varies enormously from person to person, and even in the same person at different periods of his life.

Anxiety is more frequently and clearly accompanied by physical symptoms than any other affective state.

Morbid irritability, excessive lability of mood and inability to control the instincts and affective reactions is a characteristic of psychoneurotics in general.

When phantasy is allowed full play, thinking is not concerned with actualities, but follows the direction indicated by instincts and affects.

DISCUSSION by Edward A. Franklin, Los Angeles; Aaron J. Rosanoff, Los Angeles; Josephine A. Jackson, Pasadena; Joseph Catton, San Francisco; Clifford W. Mack, Livermore.

IN THE consideration of any disease, as to its nature, its course, and its probable outcome, as well as in its management, *the wise physician will study the patient as a whole.* By no means the least important factor is his mental make-up, particularly on its emotional side. The English word "emotion" is approximately equivalent to the German "affekt," which Ebbinghaus defines as: "Feelings which depend upon the mediation of associatively awakened conceptions, and at once appear in comparatively great intensity, are called affekts." According to Bleuler, every psychic process is divisible into an intellectual and an affective side. Under "affectivity" he considers collectively affects, emotions and feelings of pleasure or displeasure, regarding the term "feeling," sometimes applied to this group, as misleading, since it is used to mean both ordinary bodily sensations and complicated cognition processes, whose elements are by no means clear to us. Affectivity varies enormously in different individuals. Its roots descend to the lowest strata, it dates back to the earliest beginnings of mental life. "It contains everything in the way of feeling tone which the mental processes acquire at the same time that they are passing from simple sense impressions and image formation through abstract conceptions and reflexion to decision and to motor impulse" (Kretschmer). Biologically, it stands in close relationship to instincts and temperament.

The instincts of self-preservation and self-perpetuation through securing food, through the avoidance of danger, and through the sexual impulse, seem to be attributes of life itself, and are present in the lowest forms. Though their manifestations in man have become in the highest complex, they still constitute the impelling force of all his actions. With them are intimately bound up the feelings in the broad sense. In primitive man the instincts were intense and uncontrolled, while the fear of dangers both known and unknown was ever present, and

what ideas he had were under strong affective influence. The mental content is greatly influenced by affects. For this influence, H. W. Maier has proposed the name "Katathymia." We know that the thinking and the world conceptions of the primitive are much more katathymic than ours. Now, while the mentality of the civilized nations is immensely removed from that of the primitive races, the ascent has been a gradual one, and many minds still retain much of the primitive habits of thought. This is especially noticeable in children and in the mentally abnormal. While we have no exact knowledge as to the cause of the emotions, which are experienced subjectively only, that they are directly connected with some physical process, and that differences in affectivity in different individuals depend upon a difference in their make-up, seems pretty certain. The importance of temperament has long been recognized, and recent studies of Kretschmer seem to show that body-build has quite a close relationship to character, though on account of the great admixture of different racial strains, the physical types are so complex that caution is necessary in drawing conclusions as to this. The relation between the endocrine glands and body structure is undoubtedly close, but as a matter of fact our knowledge as to the internal secretions is as yet fragmentary. We are by no means sure that they are exclusively products of the glands which we have recognized anatomically, and it seems not improbable that many, if not all the body cells, are capable of producing substances which are necessary for the organism. Hence, while we are justified in the opinion that affectivity is intimately related to physical constitution, we cannot make it an affair of any one set of organs.

While in the James-Lange theory of the emotions physical changes are considered the cause, the emotions the effect, the experiments of Pawlow, Cannon and others show that feelings such as pain, hunger, fear and rage, are followed by bodily changes, especially by altered glandular functioning. In their view, this is the result, not the cause of the strongly affective tone which characterizes such feelings. It has been pretty well established that in animals the mechanism regulating the physical expression of the emotions is situated in the archaic portions of the brain in the neighborhood of or below the thalamus, and Cannon locates the center regulating the adrenal secretion close to this. He believes that the impulses sent out from this center pass through the sympathetic nervous system. Emotional excitement in man is attended by many of the signs produced in dogs and cats by stimulating the adrenal center. Under excitement the heart beats rapidly, the blood pressure rises, the pupils dilate, and the processes of digestion cease. Cannon regards it as probable that "the adrenal glands, the liver, and the thyroid are as much involved in the complex of emotional response in the human as they are in the subhuman groups." As we lack proper tests for adrenal and thyroid secretions in the natural state of the body, we cannot get direct evidence of their presence or absence, hence of increased or decreased glandular activity in man. As indirect evidence, hyperglycemia or glycosuria has been noted after great emotional stress, as in football players after a hard

game, in students after a trying examination, in aviators and in citizens after a bombardment, while hyperglycemia has been reported in mental disorder with great anxiety. The influence of strong emotions in hyperthyroidism is pretty well established. By adrenalin injections many of the visceral changes of profound emotion can be produced. Persons subjected to these complained of nervousness, trembling, oppression in the chest, and "feeling the heart beats everywhere," while some athletic students reported themselves as feeling just as they did before starting a race—"all worked up and on edge." One subject said, "I feel as if I were experiencing a deep emotion, but I am not at all." These statements do not point to specific effect of the visceral changes on conscious emotional experience. Since they are similar in widely different feeling states, Cannon holds that they cannot be considered as the source of the feelings experienced. To account for the affective outburst and the features which distinguish one emotion from another, we can for the present form hypotheses only. Cannon suggests that their difference in character may depend upon the "nervous pattern ingrained in the archaic part of the nervous system," and that "when nerve influences flash through these ready but unworn pathways," the result is manifested in the affects, variable and rich in feeling tone, which we know in practice. From the foregoing it is clear that the affective state exerts a profound influence upon the attitude, the expression and the speech, as well as upon the cardio-vascular and glandular systems, and the body nutrition. Conversely, affectivity is strongly influenced by physical causes, notably by disease, witness the anxiety of heart disease, the depression and irritability in digestive troubles, the euphoria of phthisis, etc. Affectivity influences our thinking, in that the force of ideas corresponding to an affect is increased, that of those unrelated or opposed is diminished, so that the tendency is to occupy oneself with those conceptions imposing themselves as important, to the disadvantage of contra-conceptions. The depressed subject is only able to see the disadvantages, the exalted only the advantages of a certain course.

A group of conceptions bound together through having been built up around a strong affect and exerting a lasting influence upon the psyche is called a complex. The assumption that such complexes existing outside the sphere of consciousness are constantly influencing both thought and action, is the central idea in the Freudian psychology, which, stripped of many of its original dogmatic assertions, is taking its place as a useful working hypothesis for the elucidation of some of the problems of psychopathology.

Affectivity varies enormously from person to person, and even in the same person at different periods of his life. It is a most important factor in the character of the individual, determining the quality and speed of the reactions, the strength and durability of the emotions. Jealousy, envy, and pride are at once personal characteristics and affects, while laziness or energy, steadiness and industry or indifference and negligence are based upon the affective make-up. Since the affective potentiality varies so

greatly, affectivity readily oversteps the bounds of normality.

Low affectivity, while perhaps safer, does not make for high accomplishment and may be in itself abnormal. While psychopaths are usually thymopaths, so are great artists, musicians and writers, of whose utility to the world there is no question. Religious conceptions are determined almost exclusively by affective influences.

It is in psychopathology especially that affectivity plays a preponderant role, but it must be considered in all branches of medicine.

Says Kretschmer, "The psychology of the neuroses is the psychology of the human heart in general. He who knows neuroses, knows mankind." The "affect dynamic" point of view must take the chief place in a strictly medical psychology, for in it we have the best working hypothesis for a study of the neuroses, the psychopathic reaction forms, hysteria and the milder schizophrenic and paranoid borderline conditions which are continually confronting all physicians.

The power of suggestion needs only to be recalled. Now, ideas without accompanying affect have little or no suggestive power. "The greater the emotional value of an idea, the more contagious it is." The suggestive influence which one person exerts upon another depends mainly upon a reciprocal affective state. In mass suggestion the affective influences are multiplied many fold, and few can resist the contagion of great religious and political movements, once they acquire a certain impetus.

It is to be remembered that not only thought, but also other brain-controlled functions, the heart, the glands, and unstriated muscle, are under the influence of affects, so are subject to suggestion.

The so-called auto-suggestion depends entirely upon the action of the affectivity upon the logic and the body functions of the individual.

In hypnosis the associations are so limited that only things suggested by the operator are perceived or thought of; hence, those associations desired are more than usually under the control of the psyche. "The hypnotized person comprehends what is expected of him better than normally, and can utilize sense impressions ordinarily too weak for him," so that objects are so vividly conceived as to be hallucinated, while actual perceptions are kept out of consciousness, "negative hallucinations."

Now, we know that in the psychoneuroses suggestibility is enormously increased, hence the peculiar susceptibility to hypnotism. In the Freudian system, the affect-accentuated complex through "conversion," "displacement," or "suppression," is considered the mainspring of the symptoms, so varied and bizarre, of hysteria. Particularly pathogenic are ambivalent complexes—that is, those characterized by an inner conflict which the patient cannot solve, hence suppresses.

While disturbances of the affects may depend upon changes in the brain or in the chemistry of the organism, a certain constitution, usually congenital, seems to be a prerequisite in most cases. The hysteric and the paranoiac are born different from healthy people.

In all mental diseases, the symptoms—at least at some stage—are largely determined by the affective

condition; most marked is this in the manic-depressive group, the affective psychoses par excellence.

Depression is a normal reaction to misfortune; it is only when it is unmotivated, excessive or unduly prolonged that it becomes pathological. In the melancholic all but depressive ideas are suppressed, thinking is painful, and retardation may be so extreme as to give the picture of stupor. A common accompaniment of depression is anxiety, which, however, may occur in other conditions and from various causes. In some cases it is clearly connected with deficient oxygenation of the tissues, as in diseases of the heart, the blood or the respiratory organs. Freud has emphasized its connection with the sexual impulse which, when excited and unsatisfied seems to be "transformed" into anxiety. We know that normal sexuality has a certain anxiety component, and that an orgasm may occur in certain anxious situations, while anxiety attacks may be translated physically as hunger, profuse sweating, asthmatic seizures, diarrhea, vertigo, etc. There are physical causes at present unknown to us which produce depression, the patient being aware of no reason for it. In his search for a cause, he may attach to it some conception, which is clearly an afterthought, but when the falsity of this is demonstrated to him he is apt to make some new connection as long as the anxiety state continues.

Anxiety is more frequently and clearly accompanied by physical symptoms than any other affective state, often by precordial distress, pain running down the left arm, palpitation, pulsation in the abdomen, a "streaming toward the head," pressure, etc., "precordial anxiety." Anxiety tends to raise the blood pressure. An increased tonus of the pharyngeal muscles causes a distressing feeling of constriction which may lead to refusal of food. Depression occurs in various psychoses. With advancing age and the onset of circulatory disturbances, the tendency to anxious excitement increases.

Anxiety is an important accompaniment of phobias and imperative conceptions and acts.

Exaltation may vary from a natural and motivated reaction through simple euphoria, in which the feeling of happiness and well-being is not justified under the existing circumstances and is unduly prolonged to the most exaggerated self-feeling with unbounded increase of the aspirations and pretensions. When to this there is added flight of ideas and motor impulsion, we have a condition of mania. Here lability of mood is the rule, the affective condition varying with the theme, from exaltation to depression, but speedily returning to the basal euphoria. The manic picture may be an episode in many psychoses, but in its typical development is a part of the manic-depressive psychosis.

Since the symptoms just discussed may, in their milder forms, occur with a minimum of mental disturbance they naturally come under the observation of the general practitioner, who should be alive to the possible affective origin of certain puzzling visceral symptoms.

Morbid irritability, excessive lability of mood and inability to control the instincts and affective reactions is a characteristic of psychoneurotics in general, of many of the high-grade defectives, and of those borderline cases which have been brought to

gether under the general name of "Constitutional Psychopathic Inferiority." These last, the "half-insane," constitute one of the most serious problems with which we have to deal. Always dissatisfied, mostly complaining, and often in trouble, they furnish a large contingent of the criminals and "ne'er-do-wells" of the community. They are among the clients of every general physician, often never come under the specialist and can rarely be committed as insane, so remain for years a care to their friends, a nuisance to the community, the drones in the hive of industry, if nothing worse. In the foreground of their characteristics stand affective abnormalities. Even if their intelligence is average or high, it has little regulative influence upon their conduct.

Strong affects may lead to disturbances of consciousness in psychopathic individuals; for example, to the sudden explosions of blind rage, often followed by amnesia, seen in prisoners and in the feeble-minded. In other instances the affect instead of exciting, inhibits, leading to a form of stupor, seen especially in children and in young people when confronted with an emotionally charged situation, such as an examination or other task toward which there is a strong aversion or a sense of impending failure. "Affect stupor." Such situations, inner conflicts and improper attitudes, arising upon the basis of injured self-feeling, are at the bottom of a number of peculiar and anti-social acts of children, as has been abundantly proved by the newer investigations of child behavior.

Under the head of "Psychopathic Reaction Forms" or "Situation Psychoses," Bleuler has brought together such diverse conditions as paranoia, the persecutory delusions of the deaf, querulant insanity, induced insanity, reactive disturbances in prisoners, "primitive reactions," reactive depressions and exaltations, the impulsive insanity of Kraepelin, reactive character alterations, and the whole group of the psychoneuroses. "In any disturbance within the psyche, affects act differently from before and can produce morbid syndromes." "Congenital anomalies, injuries and diseases of the brain, disturbances of nutrition, intoxications and infections, and finally the prolonged action of affects, form, in varied array and admixture, the basis upon which these reactions occur" (Bleuler). It is true that similar reactions may occur in such diseases as schizophrenia and organic psychoses, and are then attached to the proper symptomatology of these diseases. Most of these syndromes are due to the exaggerated action of affects, affectivity being unusually responsive and readily brought to bear upon the associations, while reflective power is defective.

When phantasy is allowed full play, thinking is not concerned with actualities, but follows the direction indicated by instincts and affects. Characteristic of this, the "autistic" or "dereistic" thinking of Bleuler is, that in it conflict with the truth is disregarded, the "logic of the emotions" being followed. While this method of thinking is characteristic of children and primitive people, it is never entirely absent and answers to needs both affective and intellectual, particularly in fields in which we have no exact information (as in religious and philosophical speculations). It is in fact within

limits a prerequisite of intelligence, for out of free imaginings new ways are often developed.

In no form of mental disease does autistic thinking play a greater role than in schizophrenia (dementia precox) among the basal symptoms, of which disturbances of associations are of special importance. In this weakness of association, affects exert a preponderant influence upon the course of thought. In the severer forms of dementia precox, "affective dementia" is the most striking symptom. While it is not probable that affectivity is ever entirely extinguished and even very active manifestations of it occur at times, especially in the earlier stages, these patients impress us in general by the indifference of their demeanor, one of the surest signs of the disease being defect in modulating the emotions, an "affective rigidity" (Bleuler). Such patients manifest no reaction in response to a usually affect-exciting occurrence, or react with a wrong manifestation, laugh at bad news, weep at good news, etc., "parathymia." Even a usually dull patient may, however, give an adequate reaction upon the exposure of a painful complex. What affective reactions occur are usually unnatural, exaggerated or theatrical, do not impress us, and these patients seldom respond to *our* emotions, hence the difficulty in feeling ourselves "en rapport" with schizophrenics.

In epilepsy affective reactions are pathologically strong. An existing affect lasts unusually long, and is with difficulty displaced by new impressions.

It is clear that affectivity contains many elements, that it varies immensely in different individuals, and must be considered in estimating both mental and physical symptoms. We have no means of measuring it.

However, any physician who will cultivate the habit of studying the mental characteristics of his patients while judiciously questioning them can learn to form a good practical estimate as to their relative affectivity.

The control of the emotions, through the banishment as far as possible of disturbing or exciting influences (by quiet and isolation), the conveyance of favorable suggestions, especially through a calm and hopeful attitude on the part of physician, nurse, and family, supplemented when necessary by the judicious use of drugs and other measures for the control of pain, excitement and insomnia, cannot but have a favorable effect upon our results, both medical and surgical.

1060 South Broadway.

DISCUSSION

EDWARD A. FRANKLIN, M.D. (411 Bank of Italy Building, Los Angeles)—The importance of affectivity cannot be overlooked because of its practical bearing on the treatment of difficult patients. Peculiar affect states put obstacles in our path.

Affectivity is closely entwined with character and emotion, and the James-Lange theory of its physical basis is most to be depended upon.

While heredity and environment play a most important role in influencing affectivity of a given normal individual, we must not overlook such important objective factors as diurnal variations, changes of climate, changes in barometric pressure, etc., and in the pathological individual changes produced by disease.

Affectivity is undoubtedly influenced by a great many factors mentioned by Dr. Allen, but there is nevertheless

a certain constancy of affect states in individual instances, as illustrated by the faculty of memory.

Disordered relationship between normal nutritional elements of the blood system and its proper utilization by nerve tissues gives rise to dysfunction on the part of the nerve tissues, and may readily cause affect changes.

Affectivity may also be influenced to a great degree mechanically by interference with the circulation of the cerebrum and chemically by pathological nutriment of the central nervous system induced by metabolic, toxemic infective, parasitic, autotoxic, endocrinic, blood dyscrastic and other states which seriously deprive the neuron of proper nourishment.

The affective state is purely subjective and, while different stimuli show differences in the affective state, still these differences are peculiar to the individual, although they may vary slightly under normal and greatly under pathological conditions.

The affective state can be submerged by suggestion and hypnosis, and these measures are of undoubted importance in treating abnormal affective states. Strong affects are particularly noted in mania, delirium, fevers, and all congestive states of the viscera due to cardiac diseases or lowered sympathetic tone, while weak affects are more marked in dementia, stupor, melancholia, anemic states or anything which impoverishes the nutriment of the cerebrospinal system.

Interchangeable affective states from strong to weak or vice versa is a common occurrence in many diseases of the central nervous system.

AARON J. ROSANOFF, M. D. (Westlake Professional Building, Los Angeles)—I should like to emphasize what Dr. Allen has already touched upon, namely, the effect that strong emotions, especially depression and anxiety, have upon the physical condition of patients. I am thinking particularly of involutional melancholia and allied conditions. In such cases, clinical experience fully bears out the experimental researches upon animals made by Cannon. Every psychiatrist is familiar with the almost invariable loss of appetite and progressive loss of weight which are to be attributed, I presume, to diminution and alterations of the secretions of the digestive organs and to diminution of gastric and intestinal motility. Unless the physician anticipates the threatened impairment of nutrition in the early stages of involutional melancholia, and secures for the patient rest, isolation, and adequate feeding by means of milk or other easily digested food given in small quantities at frequent intervals, but furnishing in the aggregate a sufficient total caloric value, the duration of that disease will be needlessly prolonged and its mortality will continue to be high.

It seems probable that hyper-adrenalism has something to do with abnormally intense emotional manifestations, such as are seen in manic-depressive psychoses. At any rate, I have been often struck with the abnormally large size of adrenals in many of the cases which I have examined at autopsy, and occasionally I have seen hyper-nephromata either in the adrenals or in the kidneys. It may be that in cases of this kind some of the adrenal tissue should be excised, just as we excise thyroid tissue in cases of hyperthyroidism. So far as I know, this has never been attempted, and I doubt if our knowledge of the relationship between adrenal hypertrophy and excessive emotional manifestations is sufficient today to justify such surgical interference. I mention this solely for the purpose of interesting those who have opportunities of performing autopsies upon cases of manic-depressive psychoses and involutional melancholia, so that eventually we may have such accumulation of evidence as would justify attempting radical procedure.

JOSEPHINE A. JACKSON, M. D. (1955 Morton Avenue, Pasadena, Calif.)—The topic timely, the subject matter exhaustively handled, the application practical—this is what we can always count on from Dr. Allen. "By no means the least important factor in the study of the patient is his mental makeup, particularly on its emotional side." Affectivity varies enormously in different individuals, and upon its degree and kind depend the power of adaptation of the individual to life.

Primitive man listened to his solar plexus, his feelings. Modern man is supposed to be governed by ideas, the cold product of the brain cortex. But the basal ganglia,

whose peripheral extension is the solar plexus, do by their proximity to the cerebrum give to every idea some warmth of feeling, some specific feeling tone.

His affectivity varies for the individual at different periods of his life, and in response to varying states of physical health. The chemistry of the body at the moment has its effect upon affectivity. No man commits murder on a full stomach; nor is a man held accountable for what he does in hot blood. Oliver Wendell Holmes asks pertinently whether the betting would be even if the prizefighter had indulged in a purgative on the eve of the fight.

"Is life worth living?" depends not on the liver alone, but on all the glands of internal secretion, for as a man feels so do his impulses flow. "Affectivity influences our thinking." An affectful idea holds the attention. The manic-depressive swings from pole to pole in his thinking as the chemistry of his body gives him the *feeling* of exaltation and again gives him the awful torture of depression.

A complex, what is it? "A group of conceptions bound together through having been built up around a strong affect and exerting a lasting influence on his psyche." "Guard well thy thoughts," for inevitably they build themselves into complexes.

The "affect-dynamic"—the point of departure for all studies in medical psychology. "The affect-accentuated complex is the mainspring of the symptoms—in the psycho-neuroses."

JOSEPH CATTON, M. D. (209 Post Street, San Francisco)—Dr. Allen's paper appeals to me because it demands consideration of the qualitative as well as the quantitative side of mental makeup. Contrast the quite due importance he gives the affective states with the often too great importance assigned to quantitative-intelligence-scaling. A mental rating has definite value, but tells but a small part of the story. One may get along with a mental defective rating if his affective side gives proper emotional attitude towards his surroundings and expresses itself in good moral makeup and personal appearance. Mental tests leave out affectivity entirely. Allen has shown that the emotional and the quality side cannot be neglected. He finds the influence of affects on mental content, but indicates that such influence is more marked lower in the scale—in primitives, children, and mentally abnormal. This last statement is only correct on the surface. I would stress the point that the *affective states are none the less active in the average civilized adult today* than in the savage, the child, or the insane. Intelligence is an overlay which has hidden, modified, guided, inhibited, and controlled affectivity in a measure; and in turn, intellectual activity has been modified, guided, controlled and made to serve affectivity. Increasing intelligence will not destroy affectivity; hence Allen's paper.

CLIFFORD W. MACK, M. D. (Livermore, Calif.)—*The great problem in medicine has always been and ever will be the conversion into useful agents of those theories that are proven experimentally.* Dr. Allen has given us a very clear resumé of the current thought and theory regarding affectivity, pointing out what can be given application in medicine. Psychopathology is like a laboratory searching for the truth about mental mechanisms. We as physicians wish to take the product from the laboratory and use it in our work-a-day contact with patients. How best to do that is the question we need answered. I think Allen's paper will help us along the road to more efficient application.

The study of the "human organism as a whole" is a most important principle to guide us in our work. In the survey of a sick person with either a physical or a mental illness, the various physiological functions are studied and their efficiency determined with such scientific exactness as we now possess. We are interested in the condition of the circulation, the renal function, the memory, and intelligence; so, in like manner, we should study the affectivity of our patient and the sum total of its influence upon the other physiological systems. The fact that thought itself is influenced and possibly conditioned by affectivity, that moods arise from associated memories in subconsciousness, that a complex may be projected into consciousness as a subjective symptom, all demand alert-

ness on the part of the physician in dealing with the complexity of disease.

Our knowledge of affectivity is of practical importance in diagnosis, treatment and prophylaxis. In gathering data for diagnosis we find that subjective symptoms may be the product of an emotional defect or their intensity may be increased by a particular state of feeling. Whether we believe in a physical origin of the emotions in the basal ganglia or the endocrine glands, we can all agree that the character of symptoms is influenced by the prevailing mood. A peripheral stimulus may only be sufficient to register discomfort, but in an emotional depression it becomes a pain, because the receptivity of the sensorium is increased. The neglect of this fact may lead us astray in diagnosis. In treatment our course of action is influenced in the same way. Despite the theories of emotion, we have all observed clinically the effect of the emotional reactions on the vital organs of the body. Dr. Allen mentions the bearing this has on the action of the brain, heart, unstriated muscles, secretory glands, etc. This is so positively demonstrated in the pathologically depressed patient that we must accept it as a fact. In every disease, then, we should consider the factor of emotions, retarding or accelerating reparative processes, nutrition, immunity production, and glandular function. Dr. Bush of the Arroyo Sanitarium tells me that the prognosis of pulmonary tuberculosis is greatly influenced by the patient's mood. Then looking at the problem from another angle, if the depression is primary, the secondary dysfunction of vital organs demands treatment. Psychic treatment alone is not sufficient, but should be supplemented by supportive therapeutic measures to prevent metabolic disorders, such as diet, drugs, and physiotherapy.

The prophylaxis of disease in general is intimately bound up with the affective mechanism of the mind. There is probably in the incipency of every organic disorder a period of functional weakness in the particular tissue that may be influenced by the emotional balance. This phase may not come under medical observation before symptoms are registered. It is noticeable in the neuroses and psychoses, which are purely functional in type. The somatic symptoms of the depressions, which quickly disappear with the oncoming elation, as well as in the opposite course of events, illustrate this point. The emotional overstrains acting over long periods of time are psychic toxins that ultimately may precipitate a neurosis or a disturbance of metabolism. The masterly control of the affective side of a patient's life then becomes a potent agent in the prevention of disease.

As our ability to apply these truths increases, our service to our patients will be augmented.

Cyrus C. Sturgis and James A. Greene, Boston (Archives of Internal Medicine, October 15), discussing the "Nutritional Changes in Exophthalmic Goiter: The Effect of Lugol's Solution," find that:

"A comparison of the body weight of these sixty-five patients with the standard weight tables shows that 80.2 per cent. averaged 18.2 per cent. below normal when they first appeared at the hospital. A study of the alteration in body weight following operation in thirty-six patients who had not been treated with Lugol's solution and therefore were operated on with an elevated metabolism, averaging +39, showed that all except one, in whom the weight was unchanged, lost an average of 5.2 per cent. of their preoperative body weight in an average of eleven days after the operation. The factors responsible for this loss of weight might be several, but it was concluded that the most important was the combination of the inability of the patient to consume normal quantities of food and the elevated metabolism, which may remain high for a period of ten days or longer following thyroidectomy. A second group of twenty-eight patients, who had been treated with Lugol's solution and in whom the metabolism was reduced to an average of +21 before the operation, was studied. In these patients, 18 per cent. had actually gained weight by the tenth post-operative day, and the loss of weight for the entire group averaged only 2 per cent. This loss is even less than the average decrease in body weight following operation in a group of twenty-five patients with colloid goiters and non-toxic adenomas.

THE CORRECTION OF FLEXION, ADDUCTION, AND INTERNAL ROTATION DEFORMITIES OF THE LOWER EXTREMITIES, RESULTING FROM CEREBRAL PALSY OF CHILDHOOD.

By RICHARD H. PYLES, M. D., Los Angeles

The treatment of adduction, flexion, and internal rotation deformities of the lower extremities, and without which nothing can be accomplished, is physiological rest.

The most efficient means of establishing physiological rest, the first and most important factor in the treatment of cerebral palsy, is the plaster of paris cast, which should be applied in all types of deformity as soon as the patient is seen. A decided relaxation is noticeable within twenty-four hours, and a general improvement will continue with the aid of proper systemic care up to the point actually produced by the brain lesion.

No operation yet devised has ever effected any reciprocal improvement in the affected muscles that have lost their cerebral control. Realizing that we have not a motor paralysis, but a destruction of the mechanism which governs voluntary expression, surgical interference is never indicated unless we have actual structural deformity to correct that cannot be overcome by manipulation under anesthesia.

DISCUSSION by George Rothganger, Oakland; Harry J. Schott, Los Angeles; Frank A. Lowe, San Francisco.

CEREBRAL palsy of childhood, if our present knowledge of the primary pathology and nature's processes of repair are correct, is an incurable condition in which the brain has been retarded in its normal development by some injury which has either partially or totally destroyed its anatomical and physiological integrity. These destructive processes, striking as they have the main switchboard from which all thought and action is distributed, puts the entire system in a state of chaos. The diagnosis is easy because every patient presents many of the classic symptoms that have been described for the disease.

With the familiar picture in mind, I shall not dwell further on an academic discussion of why and how this all occurred, but will direct my remarks toward the best method of administering justice to the patients by assisting them to make the most out of what they have left. This can only be done in three ways: by (a) localizing the focus of disease or lesion in the brain and attempting, through surgical treatment, to open up some of the natural channels of repair; by (b) physiological rest and exercise, administered according to the vital requirements of the patient, and by (c) making an effort to prevent or correct the deformity which has occurred as a result of the primary lesion.

The first has not met with very much success, except in a few isolated cases that have been treated early and where the continuity of the nerve fiber and its adjoining cell have been embarrassed by pressure from without rather than by destruction of some part of the brain. Where extravasations of the blood have penetrated between the covering membranes of the brain, and in some cases where the injury to the motor, sensory and spinal centers in the cortex are not extensive, skillful surgical treatment soon after the injury has been responsible, rarely, for gratifying results. I believe that most neurological surgeons will agree with the statement that our natural biological laboratories of repair cannot be helped in their work very often where the lesion has been one of long duration from the

cause just mentioned and never where any part of the cerebrum, its trunk, or axis have undergone pathological changes, brought about by developmental alterations in utero or any form of cerebrospinal meningitis after birth. Bearing this in mind we turn instinctively to the second and third methods of helping these sufferers, which brings me up to the subject of this discussion.

The treatment of adduction, flexion and internal rotation deformities of the lower extremities—The most important factor of such treatment, and without which nothing can be accomplished, is physiological rest. When we realize how difficult this is to obtain in a patient with a normal brain and communicating system, we will at once realize the vastly increased difficulties that confront us in our effort to produce rest in patients with many of the association fibers that deal with psychical function and the motor centers of the cerebral cortex either partially or totally destroyed. We must realize that the end-result will be compatible only with our understanding of the abnormal condition and our ability to intelligently direct this knowledge to operate in the patient's behalf. The treatment, therefore, cannot differ materially in any of the classic types recognized as monoplegia, hemiplegia, paraplegia, and diaplegia, because they express to us merely degrees of brain impairment, which may be permanent and progressive, or may be temporary, but which can only be modified by appreciating the requirements for natural repair.

The effort that is constantly and systematically carried to effect normal function through the channels of a defective mechanism is responsible for an expression of disassociated and exaggerated movement that is productive of deformity and the formation of toxic elements which flood the system when the inhibition of the higher centers is impaired or lost. Consequently, we have not alone the actual deformity, which will always be permanent to deal with, but an apparent condition which is responsible for the thermic and vasomotor expressions produced by the fatigue toxins on a highly sensitive, sympathetic nervous system. The histories of my 155 cases studied during the last five years may not be entirely accurate. However, they are sufficiently so to signify a reasonably definite knowledge of the primary cause. Sixty-five per cent were due to cranial injury at the time of birth, or shortly after. Fifteen per cent were due to improper development of the fetus in utero or from some systemic derangement of the mother, 10 per cent to cerebrospinal meningitis during the first two years after birth, and 5 per cent unknown. There were nine cases of monoplegia involving the right leg, two cases involving the left leg, two cases involving the left arm, forty-six cases of hemiplegia of the left leg, twenty-nine cases of paraplegia involving the lower extremities, and twenty-six of diaplegia. The treatment of this group has been routine, irrespective of the intelligence or mental age of the patient.

The patients suffering from speech defects have been given special training under the supervision of Dr. W. G. Stivers, and the endocrine balance under the care of Dr. Clifford A. Wright.

In the department of neuropsychiatry, the mental

age and capacity of the patient is recorded before entering the department of orthopedic surgery. Until recently this department has not been consulted in determining the operability of the patient, but as experience teaches the impossibility of satisfactory post-operative training in the most extensive types of cerebral destruction, no patient at this time is recommended for surgery that cannot pass a grade of 50 per cent or better under the standard classification. Upon this basis about 75 per cent of the following patients have undergone some form of surgical operation to improve or correct their abnormalities, not including work done on the upper extremities.

Twenty-five cases of thigh flexion contraction were operated by Souter's method. An incision, beginning just above the anterior superior spine, is carried vertically downward for about three inches, the fascia is incised transversely down to the great trochanter, and the anterior and inferior superior spines are separated from the ilium, together with their muscle attachments. The thighs are then hyperextended and abducted. The procedure lessens somewhat the traction at this point. Where the thigh adductors are contracted they are tenotomized, a condition which is present in most cases of the paraplegic type that have not been treated, as well as in many cases of hemiplegia. Knee-flexion deformities, produced by the overacting hamstrings, were treated by the Robert Jones technique in fifty-five cases. The biceps is removed at the point of its insertion from the head of the fibula and dissected up to a point about the middle of the femur. From this point it is carried forward and downward over the fascia lata and inserted subperiosteally through a raised flap into the center of the patella. Thirty-five cases of this operation were performed by me and the end-results closely observed. Three cases of this deformity have been treated by the method described by Stoffel, which attempts to reduce the power of the overacting muscles by dividing the nerve of distribution to the muscle itself. I have not had sufficient experience with this operation to make a positive statement as to its relative merits, but in one case in which the Stoffel procedure was done on the right and the biceps was transplanted on the left, together with a tenotomy of the thigh adductors, I find that voluntary movement in the left leg is much better at this time.

The foot is generally in a position of talipes equino varus, unless it has been previously corrected, or the achilles tendon has been tenotomized at an earlier date. For the relief of this deformity, the E. P. H. tendon is transplanted into the head of the first metatarsal, the tibialis anticus to the outer border of the foot and, in some instances, the tibialis posticus into the insertion with the peroneus brevis; in others, a subastragaloid arthrodesis was done. Contracted plantar fascia has been treated by the method described by Steindler, in which all of the attachments are loosened from the os calcis. Arthrodesis operations on bone that have not completed their ossification are not very satisfactory.

The equinus in all of our cases has been treated by a tendoplasty to lengthen the achilles sufficiently to overcorrect this type of deformity, and never by a tenotomy, as the tibialis anticus and the pero-

nei will frequently take up the pull when the tension from the opposing extensors has been released, producing the opposite deformity, especially if the patient's weight is borne upon the foot without the support of a brace provided with a 90 degree down-stop at the ankle joint. All of these patients, without exception, have been placed in plaster of paris casts at the time of the operation. If the deformity is confined to the foot, either a full or short leg cast is applied, but in all cases involving the thigh flexors, adductors and internal rotators, a body spica is applied, with the legs abducted as far as possible. Suitable braces are fitted as soon as wounds are sufficiently healed to permit, which is generally from four to six weeks after operation. Physiotherapy, including suitable muscle exercises, is begun at this time in an effort to encourage voluntary control.

CONCLUSION

The most efficient means of establishing physiological rest, the first and most important factor in the treatment of cerebral palsy, is the plaster of paris cast, which should be applied in all types of deformity as soon as the patient is seen. A decided relaxation is noticeable within twenty-four hours, and a general improvement will continue with the aid of proper systemic care up to the point actually produced by the brain lesion.

No operation yet devised has ever effected any reciprocal improvement in the affected muscles that have lost their cerebral control. Realizing that we have not a motor paralysis but a destruction of the mechanism which governs voluntary expression, surgical interference is never indicated unless we have actual structural deformity to correct that cannot be overcome by manipulation under anesthesia.

Reducing the power of the contracted muscle or muscle group by surgical treatment will afford temporary relief by converting the strain to groups that have long been in subjection, but unless the defective extremity is held in a neutral position by some form of fixation dressing, a deformity opposite to that corrected will develop in a very short time.

Neither the accurate mental age nor the extent of the brain lesion can be determined until the general nutrition of the patient has been improved and the circulating toxins reduced to a minimum. The patient must be thoroughly relaxed and accustomed to his or her environment.

None of this series of cases under the most efficient care have made any change in their mental capacity ratio. Experience by personal contact and educational advantages that minimize the strain on the emotional centers improve the patient by developing a communicating system with the unimpaired part of the cerebrum. The result depends upon the scope of the decerebration.

1052 West Sixth Street.

DISCUSSION

GEORGE ROTHGANGER, M. D. (4501 San Pablo Avenue, Oakland, Calif.)—In this paper Dr. Pyles presents an enviable experience in spastic paralyses. He deserves much praise for his efforts to follow up the cases under the unfavorable conditions indicated.

I feel that the author would have added much to the value of the paper if he had expanded it for publication. The therapeutics is devoted almost entirely to the technical

side of certain surgical measures. The orthopedic treatment which preceded operation, except routine plaster of paris, has not been mentioned. It would be of value to know in more detail the reasons which led Pyles to select the several operative procedures that he did, and to know what his after-treatment was and for how long continued. One sentence would indicate that he believes all cases should be treated by open operation, except "where the vitality of the patient would not permit."

Operations directed to the relief of spasm have value only as they aid in the re-education of the muscles, and it is this re-education which is the real agent by which improvement is secured. Fixation with plaster of paris in the immediate post-operative period is of much value. But prior to determining the necessity for operation and in the very long, late post-operative period, well-constructed splints are preferable, for in them there is an opportunity for exercise of the weak antagonists of those affected with spasm, and one may thus avoid the atrophy of the complete fixation by gypsum.

HARRY J. SCHOTT, M. D. (1209 Brockman Building, Los Angeles)—In considering the treatment of spastic cases the surgeon must face a problem too often neglected and hurriedly passed over, as offering a hopeless prognosis or, at best, very poor results. One should not accept this type of case for treatment unless he be willing to devote to it prolonged and diligent care. The monetary expense to the patient is heavy, and one may be inclined to consider the end not justified by the means. The object of treatment, whether it be surgical or medical, is to establish voluntary control of muscles and co-ordination of movement. If the child is unable to walk we should attempt to get him on his feet, even if it be by means of braces and crutches. If he can be taught to help himself it is a benefit to him, as well as a heavy burden lifted from the family and attendants who must care for him.

I wish to emphasize the importance of the point made by Pyles of the great value of physiological rest, careful attention to physiotherapy (including muscle re-education), and to the correction of speech defects. Surgical treatment is indicated in certain selected cases, and the choice of methods depends, of course, upon the conditions present. It has for its object the restoration of muscle balance. Atrophic contractures, which do not relax under anesthesia, must be corrected by tenoplasties or tenotomies. The spastic contractures can be dealt with by either the muscle transplantations or by attacking the motor nerves by the Stoffel method. I believe that the Stoffel operation of neurectomy, in appropriate cases where the proper amount of nerve has been resected, and where the careful, diligent treatment is carried out, will give us better results than any of the other single procedures.

In our management of these patients our problem must be squarely met. Even though our results may not be brilliant in many, they will, in the vast majority, justify our efforts.

FRANK A. LOWE, M. D. (Flood Building, San Francisco)—My experience has been that considerable time has elapsed from the time of the occurrence of the palsy until the patient comes into the orthopedic surgeon's hands for care. The parents, relatives, or friends have consulted one or more physicians and met with discouragement. Frequently, the various cultists also have had their chance at curing them.

Due to the lapse of time, an operation for the relief or cure of the primary lesion is futile. The damaged area is irreparable, and any attempt on the part of the surgeon to eradicate it would only do further injury. In the upper extremity I find that braces or appliances hinder the progress toward recovery. So I depend upon physiotherapy, including active and passive massage and the training of certain groups of muscles to perform certain kinds of work. In the lower extremity it is more difficult to bring about a pleasing result on account of the definite function of supporting the body weight that must be performed. The adduction deformity of the lower extremity is corrected by a tenotomy at the knee by open incision and tendon elongation. The knee-flexion deformity, due to the overacting hamstrings, is corrected by a tendon lengthening of the various tendons involved by an open operation and sutures. The knee is put up in a plaster of paris dressing in an overcorrected position.

The talipes equinus deformity is corrected by subcuta-

neous tenotomies of the plantar fascia and tendo Achilles (Sayre), no sutures or stitches being used.

The subcutaneous tenotomy of the plantar fascia gives equal if not better results than the Stiedler operation and lessens chances for infection and scar formation, either one of the latter hazarding the chances for a good result. After the above tenoplasties and tenotomies are done and surgically dressed, the extremity is brought to an overcorrected position and put in plaster dressings, the parts being first padded with good absorbent cotton properly shaped and bandaged firmly but not tightly with a sleazy gauze bandage. Over this dressing is applied the plaster. Good absorbent cotton adds warmth and comfort to the parts, does not wrinkle, prevents pressure sores, and takes up moisture from the skin. The cast is fenestrated over the sight of the tenoplasties, allowing the latter to be dressed and the removal of stitches when open operation is done. The cast is split anteriorly its entire length to avoid constriction of the parts covered. Two weeks post-operative I find that these patients do better by removing the first dressings applied with the parts in overcorrection and followed by reapplying new casts, with the foot at a right angle to the leg and the knee slightly eased forward. The patient can walk in these dressings readily after a few days, with or without crutches, and enjoy life anew. At the end of four to six weeks the casts are removed and the foot, leg, and thigh modeled (depending upon the severity or extent of the involvement). From the model a proper brace can be made to support the extremity where needed. The casts are again applied and the child permitted to still further improve in the retaining dressings, until the appliance or brace is finished; then the casts are removed and the appliance fitted, and the child can get about with or without crutches.

I find that patients of a very nervous, irritable disposition and those who find it difficult to talk show a very marked improvement immediately after the tenotomies on the tendo Achilles (Sachs), thereby releasing the pull on the muscles and nerves.

Probably not more than once in five hundred cases is it necessary to do a tendon transplantation.

I believe that the Stoffel procedure is of much benefit in certain selected cases where there is overaction in the muscles of the thigh, but only in exaggerated cases.

Attempts at correction without tenotomy or tenoplasty are futile and cause great distress, without benefit, and in certain instances has produced a flaccid paralysis (E. H. Smith). Doctor Pyles is to be greatly commended on his most excellent presentation of the subject of cerebral palsies of childhood.

DOCTOR PYLES (closing).—In closing, I wish to express my appreciation to my colleagues, Drs. Schott, Rothganger, and Lowe for the interest they have shown in so freely discussing my paper. Answering Dr. Rothganger's question, my experience has been that *no* treatment in the more severe forms of spastic paralysis precedes the plaster of paris cast. It affords the most efficient method of controlling the patient for accurate diagnosis and logical treatment. He has suggested in his discussion that operations directed to the relief of spasm are of some value. Many of the operative procedures in this series of cases were selected with the view of relieving spastic clonus by neutralizing the pull of overacting muscles. This is an unnecessary procedure. The plaster of paris cast, applied under anesthesia, accomplishes this without surgery. I have carefully watched the treatment of many of these cases, comparing them weekly with similar pathological changes that were treated entirely by physiological rest with equally as good, if not better, end-results. In this respect I must differ emphatically with Dr. Lowe's statement that there is danger of producing a flaccid paralysis in making a correction under anesthesia without doing a tenotomy or tenoplasty. Trophic contractures should not be corrected by force, but one is surprised to find how many cases recommended for surgery can be corrected by gentle manipulation when completely relaxed. The judgment of the surgeon is of importance in this respect. A flaccid or ischemic paralysis can only be produced by excessive traction on the soft structures or pressure from the cast. As the mistake can be recognized by inspection very quickly, it can only be attributed to negligence. The general tendency has been, I think, to

do too much operating in these cases, which not only increases the monetary cost to the patient, but retards the after treatment and imposes unnecessary suffering.

The work now being done by Drs. Royal and Hunter may shed a different light on the treatment of spastic paralysis, but until we have established the permanent results to be received by sympathetic ramisection, conservatism should govern our recommendations in all cases.

METASTATIC TESTICULAR CARCINOMA INVOLVING THE ABDOMINAL MEDIASTINAL AND SUPRA-CLAVICULAR GLANDS TREATED BY X-RAY

REPORT OF A CASE WELL TWENTY MONTHS AFTER TREATMENT

By H. J. ULLMANN, M.D., *Santa Barbara Cottage Hospital, Santa Barbara, Calif*

DISCUSSION by W. E. Chamberlain, *San Francisco*; Lloyd Bryan, *San Francisco*; Frederick H. Rodenbaugh, *San Francisco*.

TERATOMA testis, while fairly uncommon, are so often malignant, and when malignant are so prone to form metastases, that we should keep any means by which their growth may be retarded, even when a complete cure is impossible, fresh in our minds. Surgery alone is insufficient except in the earliest stages, and is hopelessly inadequate when metastases have occurred. In nineteen post-operative recurrent cases seen at the Memorial Hospital, New York, orchidectomy had been performed upon eighteen. There were eight recurrences in the groin, along the spermatic cord; seven in the abdomen, along the spermatic lymphatics, and four in the lungs. In six cases more than one region had become involved.

Ewing divides teratoma testis into three main varieties:

1. Adult embryomas or teratomas.
2. Embryoid, teratoid, or mixed tumors.
3. Embryonal malignant tumors.

There are many intermediate forms connecting these types, and the same tumor may present several structures. The tumors arise, with rare exceptions, from sex cells situated in the rete testis, and the teratoma may develop either toward the testicle and epididymis, involving both in a large tumor mass, or, much more rarely, toward the epididymis, forming a typical tumor of this organ. The retroperitoneal nodes at the celiac axis are often involved through the lymph channels of the spermatic veins, and an epigastric tumor is often the first sign of recurrence. This is especially common with the highly malignant embryonal carcinomas. From this point there may be rapid progress upward, so that mediastinal and even cervical tumors may divert attention and become the largest tumors in the body. Invasion of the spermatic and iliac veins with continuous tumor growth extending as far as the heart has been observed both with chondrosarcoma and chorioma. Discontinuous metastasis by way of the veins is most frequent, and gives rise to tumors of lungs, liver, brain, kidney, and stomach.

Barringer and Dean report nineteen cases of post-operative recurrent teratomas treated by radium or

radium and surgery, with five living; 3, 12, 17, 18, and 28 months after treatment.

I have only one patient to report, but the results of treatment were so prompt and satisfactory that we considered them of sufficient interest to bring to your attention.

C. G. White. Age, 35. Was referred by Dr. Thorner of Santa Maria June 12, 1922. Two and a half years previously his right testicle had begun to enlarge and harden. A year later it was removed. The pathologists report was teratoma. Recovery from operation was uneventful, and he felt well for fifteen months, when he began to have pain alternately in the back and groins. He reported to his surgeon three months later, eighteen months after operation, who found abdominal and cervical masses, and referred him to me for treatment. The patient stated that he had noticed the cervical tumor for the first time about ten days ago. He had had abdominal cramps off and on for three or four weeks which were growing worse, and he felt that he was rapidly losing strength. The only incident of interest in the family history was that his mother died of a breast tumor at thirty-eight. Physical examination showed an exceptionally well developed and nourished man. He looked sick and presented evidence of rapid loss of strength. There was a rounded, smooth tumor in the left lower cervical region 3.5 cm. in diameter. Roentgenograms of the lungs showed a moderate, smooth enlargement of the mediastinal glands, and there was a hard, reniform, slightly nodular mass in the right abdomen, measuring not less than 12 x 20 cm. The right testicle was absent, the left appeared normal. There were no palpable axillary, epitrochlear or inguinal glands. Routine blood and urine examinations were essentially negative.

Treatment was started immediately. My 100 per cent dose is the amount of radiation delivered at 50 cm. target distance in ninety minutes, with 1 mm. of Cu plus 1 mm. A1 as filter, 200 KVP and 5 milamp. An attempt was made to put at least 90 per cent of this dose into all tumor areas. It required six and one-half hours to do this, and the treatment was completed in eight days. He returned on September 6 for a second series. At this time, eleven weeks since the completion of the first treatment, the cervical mass was about 2 cm. in diameter, and the abdominal mass was just palpable. Seventy-two per cent of the first dose was administered in four days. Ten weeks later no evidence of any tumor mass could be found. Our records of February 17, 1923, state that on that date "No evidence of tumor found at any point. Has been and is working full time—clinical cure."

He last reported April 23, 1924, and the same negative findings were obtained. Roentgenograms of the lungs have been repeatedly negative. The slight mediastinal increase has disappeared. He is, therefore, well of his tumor twenty-two months after treatment was first instituted.

No report has been obtained relative to the type of teratoma originally found, but it is fair to assume that it was of the highly malignant embryonal type, because of its rapid and extensive metastasis and its prompt response to roentgenotherapy.

Third Avenue and Bath Street.

DISCUSSION

W. EDWARD CHAMBERLAIN, M.D. (Stanford University Hospital, San Francisco)—A most valuable part of Dr. Ullmann's paper is his description of his technic in this successfully treated case of metastatic testicular carcinoma. From our measurements of Ullmann's x-ray output we have calculated that the 100 per cent dose which he mentions amounts to 1300 E. (The E unit is that amount of x-ray which will produce 2,100,000,000 ions in 1 cc. of air, enabling it to conduct one electrostatic unit of electricity.)

My patient, Mr. A. J. G., was referred to me on December 18, 1923, many months after removal of the primary growth—a carcinoma of the testicle. When referred he had developed huge masses throughout the abdomen and a marked degree of cachexia. I considered him unsuited to heavy dosage, but gave him 850 E over the

back of the abdomen, repeated the next day over the front. These doses were delivered with 200 KV (crest) 70 cm. A. S. D., 35 cm. diameter areas, filters $\frac{3}{4}$ mm. cu. plus 1 mm. aluminum. On January 22, 1924, the large tumor on the left side of the abdomen had disappeared, and shortly after this all traces of tumor masses were gone. On January 22 and 23, I gave him 565 E posteriorly and the same amount anteriorly.

On March 17, the patient reported with masses in the left neck, the right mamma, and the liver. Fluoroscopically, there was no enlargement of the mediastinum. The patient was quite weak, and I was again afraid to use large doses. I determined upon relatively small doses over a relatively wide area, and treated him from neck to pubis at weekly intervals, delivering 150 E posteriorly and anteriorly each week.

For a time there was a very rapid improvement, with all masses regressing until none could be made out except that the liver never went back to its normal size.

About May 15 ascites began to develop, and the patient rapidly went downhill again, although a month previously he had been back at his work and in much better shape. The patient died on June 9, 1924. The most striking feature of this case was the disappearance of the widespread metastatic masses under the 150 E dosage, about 12 per cent of Ullmann's 100 per cent dose.

An exactly similar case which also developed distant metastases has been treated by me at the San Francisco Hospital, with the same marvelous response to radiotherapy. Some six months after institution of treatment, this patient was in excellent general health and all masses had practically disappeared, although the dosage had been only a fraction of the maximum.

The striking result in Ullmann's patient leads me to believe that when there are no contra-indications the first high voltage x-ray treatment should be of maximal intensity. Unfortunately, many of these patients do not reach the x-ray laboratory until so weakened and cachectic as to lead us to fear the results of such large doses. I plan to imitate Ullmann's technic when the opportunity presents itself, and feel sure that earlier administration of the large doses will result in the longest possible period of arrest of the disease.

LLOYD BRYAN, M.D. (135 Stockton Street, San Francisco)—This report of Dr. Ullmann's emphasizes what may frequently be done with high voltage x-ray therapy in hopelessly inoperable cases. Tumors of this sort are many times particularly susceptible to the radiation.

FREDERICK H. RODENBAUGH, M.D. (516 Sutter Street, San Francisco)—Ullmann's results are similar to those obtained in two of my patients, except that I have used rather small dosage—about 25 per cent of the amount used by Ullmann.

It is my impression that embryonic tumors of this nature, when susceptible to radiation, do not require large doses, but a small fraction of an erythema dose is necessary. The ultimate result is usually bad; the patient succumbs to cachexia, or metastasis, which cannot be controlled. However, the gratifying palliative result encourages the study of these interesting neoplasms.

I hope that Dr. Ullmann will report the progress of this case at the next meeting.

DR. ULLMANN (closing)—The reason for giving a heavy initial radiation to this patient was to obtain, so far as possible, what we call the optimum dose. This dose is one that will produce the greatest injury to the malignant cells and at the same time the least injury to the patient. The patient in this instance was in excellent physical condition and, therefore, could stand a dosage larger than a cachectic individual, i. e., a dose large enough to be distinctly injurious to the malignancy. It is reasonable to assume that a large factor in obtaining results in this case was this ability to withstand a large dose.

Chamberlain's excellent results, I believe, were due to good judgment in his attempt to obtain what, to his patient, was the optimum dose. We have a happy result from radiation treatment when we hit upon this optimum dose, which varies with every case. Where our results are poor we probably either fail to properly estimate the dose, or it is unattainable because of unknown factors present.

EARLY RACHITIC CHANGES IN THE FEMUR AND TIBIA

By HALBERT W. CHAPPEL, M. D., Los Angeles

Although the etiology of rickets is still unknown, and its early symptoms are frequently very obscure, an early diagnosis may be definitely made by means of the roentgen rays, and treatment started before the development of structural deformities.

Full discussion by William Palmer Lucas, San Francisco; Rolla G. Karshner, Los Angeles; William Sidney Bowers, Los Angeles; H. H. Markel, San Francisco.

THE etiology of rickets—a disease which may exist without symptoms, but which early affects the structure of the bones—is not known, and it is, therefore, very difficult to recognize and study in its early stages. Of the various theories advanced, that of defective feeding seems to offer a cause in the greater number of cases, the diet being so unbalanced that it really seems antagonistic to the deposition of calcium in the growing bone matrix.

After a most thorough review of the literature, one is unable to select a diet that will prevent rickets in every person. A low-grade infection, lack of sunshine and fresh air, insufficient amount of exercise, prenatal influences, or some constitutional disorder, apparently causes rachitic changes in cases where the diet has been carefully selected. On the other hand, rickets is frequently found in a seemingly well child of healthy parents where the diet has always been well-balanced, fresh air and sunshine have been abundant, and there was a normal amount of exercise each day. Rickety children are often fat, rosy, and apparently well nourished.

In normal developing bone, the areas of ossification, and the calcification, proliferation and arrangement of the cartilage cells are definitely marked off from each other. This orderly arrangement is lost in rickety bone, as the lime salts are deficient in some parts of the cartilaginous matrix, and irregularly deposited in others. There is also a marked increase of the proliferating cartilage cell zone, which, together with an overproduction of the osteoblastic elements, results in enlargement of the bony structure, but of an imperfect character because of the deficiency of the lime salts.

The growing line at the epiphyseal junction is broader than normal, the width also being considerably increased and easily felt when the ossifying cartilages are subcutaneous. There is excessive proliferation of the osteoblastic layer of the periosteum, which increases the circumference of the bone. Under proper treatment the rachitic changes give way to a more normal process of ossification. When discovered and treated early, the rickety bone frequently shows but slight changes from normal bone.

The large epiphyses, bent limbs, large square head, Harrison's groove, rickety rosary, "pot-belly," delay in closure of the anterior fontanelle, profuse head-sweating, delayed dentition, and marked muscular weakness, give a clinical picture so striking that rickets can hardly be mistaken. However, in mild cases it is difficult to determine what constitutes evidence of rickets.

Occasionally there are no symptoms except bow-legs (genu-varum) or knock-knees (genu-valgum), which mother felt sure did not exist a few weeks

ago. More frequently, vague symptoms with gradual onset, and general distribution, do not suggest rickets until there have been sufficient changes in the bones to cause the characteristic deformities. Abnormal lateral mobility and hyperextension of the knee joint, resulting from relaxation of the ligaments and from weakened condition of the muscles, contribute largely to bow-legs or knock-knees. The latter are also aggravated by the everted feet, so frequently seen in these cases.

Occasionally there has been no decrease in activity. More often there has been for some time vague symptoms which did not yield to treatment which, however, was not for rickets. An x-ray of the lower extremities apparently would have been the only definite way of determining the cause of the symptoms. It is this type of rickets so frequently overlooked, even by excellent diagnosticians, and responding quickly and rather completely to treatment, which I wish to emphasize in this paper.

An x-ray on one plate, from just below the crests of the ilia to and including the feet, is necessary, not only to determine the changes in the femur and tibia, but to give an accurate record of the deformity. In these very early cases the greater changes are at the lower end of the femur, and upper end of the tibia. The whole joint has a hazy appearance, the shafts near the epiphyseal lines are clearer and more transparent than normal. There is also a noticeable thickening at these points. The epiphyseal lines are considerably broader and not nearly so clearly defined as normally. Usually there is an increase in the calcified material in the epiphyseal region. The lower epiphysis of the tibia and fibula show changes similar to those just described, sometimes more marked, but frequently not nearly so noticeable.

Operative interference is not indicated in any type of rickets where the bones are still soft. Nor is it necessary to subject the patient to the prolonged use of braces. During the acute stage there is hyperemia of the entire joint, which should be protected for several weeks by complete rest.

The type of rickets which has just been described responds quickly to the following treatment. Very slight changes, if any, are made in the diet, but cod-liver oil is given for several weeks. Exposure to sunshine in the open is a routine.

Corrective treatment is begun immediately. By means of thick chamois-covered felt pads, placed between the internal condyles, in knock-knees, the internal malleoli are gradually brought together while the knees are held firmly to the table. This overcorrection is maintained about five minutes, then light plaster of paris casts are applied as rapidly as possible from the groin to and including the foot.

In this way correction is obtained with the first casts, without using any pressure during their application. No weight-bearing for four weeks. Then another stretching gives full overcorrection which is maintained for four weeks by walking-casts. The muscle balance is restored by high shoes with one-eighth of an inch float on the inner side of the heels and soles, and frequent stretching at the knees. In from two to four months after removal of the casts

correction is not only complete, but the x-ray gives evidence of normal or greater density of the bones.

A simple device, fastened to the table, keeps the knees fully extended during the stretching. This is made of two pieces of aluminum, twelve inches long, five inches wide, padded with felt and covered with chamois. The lower one is fastened to the table by two bolts with thumb screws, while the upper one is held firmly against the knees by two pieces of webbing passing through each end of the pads and buckling on top.

By gradually increasing the pads between the internal condyles, marked overcorrection may be obtained and held ten or fifteen minutes without discomfort to the patient, especially if the outer part of the ankles is protected by felt pads. As the appliance which holds the knees firmly to the table allows about 5 degrees of flexion, there is no unnecessary strain to the posterior part of the knee joint during the stretching.

Since the process is much more difficult in cases of bow-legs, the following appliance has been very helpful. Two small semi-circular pieces of metal, to one side of which is riveted a strap, then covered with felt, and to the other a narrow piece of metal four inches long with several screw holes, are fastened as closely together as possible. On the other end of each strap is a sliding felt pad, to complete the circumference of the leg. This appliance, which may be gradually widened to seven inches, is strapped on just above the ankles. The feet are held markedly everted by an assistant while the knees are slowly brought to a position of overcorrection and held there several minutes.

The procedure with casts is the same as with knock-knees, but the float on the shoes is on the outer side of the heels and soles. The feet must be carefully watched and the floats removed when the first sign of weakness appears.

Although the etiology of rickets is still unknown, and its early symptoms are frequently very obscure, an early diagnosis may be definitely made by means of the roentgen rays and treatment started before the development of structural deformities.

1136 West Sixth Street.

DISCUSSION

[EDITORIAL NOTE—Ordinarily, discussions of papers are limited to five hundred words. However, an exception is made in the case of Doctor Lucas' discussion, because of the tremendous importance of the questions raised by Doctor Chappel, and because of the additional opinion brought to bear upon the question as the result of original investigation.]

WILLIAM PALMER LUCAS, M. D. (University of California Medical School, San Francisco) — Doctor Chappel's discussion of the pathology of the bone in rickets is very well expressed. I am not in a position to discuss his corrective treatment and orthopedic stand, but concerning the etiology of the disease, although the cause is still obscure, I do not think we need to be as pessimistic as one would be led to believe from Doctor Chappel's introductory paragraph. Since Mellanby published his experimental work in 1915 on puppies, many very valuable contributions to our knowledge of rickets have been brought forward, and we are in possession at the present time of means of successfully preventing and treating early rickets before deformities have occurred. We know that rickets is controlled by two masters—one dietetic, and the other environmental. In cod-liver oil, we have a specific both for the prevention and cure of rickets. The origin

of its use is obscure, but we know that its anti-rachitic properties were appreciated early in the eighteenth century. Mellanby placed the use of cod-liver oil on an experimental and proven basis. The work in this country, particularly by Parks, has shown conclusively that sunlight or the artificial mercury vapor quartz rays equally prevent and cure rickets. When one discusses, however, the fundamental question as to what prevents the deposition of lime salt in the bones, we have not arrived at a final answer. On the other hand, we have various studies on salt and inorganic salt metabolism in relation to bony development, and have accumulated a great deal of evidence.

During the past three years, Doctor Martha Jones of the University of California Medical School has been carrying on a series of experiments with puppies which has conclusively shown that the diet of the mother during pregnancy has a very marked effect on the tendency of the puppies to develop rickets. In our experience, brood bitches which are fed on a mixed food containing a liberal amount of inorganic salts give birth to normal puppies, while the same animals fed on a diet low in calcium, produce litters of puppies which have a marked rachitic tendency. These puppies frequently develop severe rickets on what appears to be a well-constituted diet. It is a well-known fact that infants, as well as animals, vary tremendously in their susceptibility to rickets. Some infants will develop rickets to a marked degree on the same diet and under identical conditions on which others develop normally. The same is true of experimental puppies. In such cases the fault unquestionably lies in the individual and not in the diet or environment. Metabolic studies conducted in our laboratory, as well as in those reported by other investigators, showed that the distribution of calcium and phosphorus between the urine and feces in a rachitic child or puppy is different from that which occurs in the normal individual—a much larger proportion of both elements being excreted in the feces of the former than in those of the latter. In rickets the alkalinity of the feces and urine is increased with a marked decrease in the retention of calcium salts. Experimentally, this condition, which ultimately results in rickets, can be produced in a puppy on a diet which appears to be adequate, in respect to protein, fat, carbohydrates, vitamins, and inorganic salts, but contains an alkaline salt mixture, and may be cured with no change in diet or environment other than the addition of sufficient HCl to neutralize the excess of alkali. Here, again, individuals of the same litter vary tremendously in their reaction to acids and alkalis. In certain individuals who develop rickets quickly and to a marked degree, very large doses of acid are required to reduce the H ion concentration of urine and feces to neutrality. On the other hand, other individuals can tolerate relatively large quantities of alkali and not excrete alkaline urine and feces. In rickets there appears to be a very nice adjustment between the acids and bases and an individual's ability to store bone-forming elements. If rickets can result from too high a degree of alkalinity in the intestinal tract, it is conceivable that this condition may be the result of an insufficiency of HCl in the gastric secretion. Those infants who have relatively little HCl may develop normally when breast-fed, but if the diet is changed to foods having a higher buffer content and potential alkalinity, such as cow's milk, the amount of acid present may be insufficient for normal mineral metabolism. Faber has shown that between 50 and 60 cc. of N/10 HCl are required to reduce the H ion concentration of a given quantity of cow's milk to a pH of 5.0, while 15 to 20 cc. of N/10 acid are sufficient to reduce the pH of a like quantity of human milk to the same value. If rickets is due to faulty absorption of the calcium salts in the intestines as the result of too high a degree of alkalinity, we can explain why artificially fed infants are more prone to the disease than those who are breast-fed. Individual difference in HCl secretion may also explain why one of a pair of breast-fed twins is rachitic and the other not.

While diet and hygiene are important factors in the production and cure of rickets, I am of the opinion that the diet of the mother during pregnancy and lactation is equally important in determining the susceptibility of an individual. Statistics show that the average American dietary is low in minerals, especially calcium. This is

particularly true of the poorer classes in large cities who cannot afford sufficient quantities of the mineral-rich foods, such as fresh fruit, green vegetables, and milk. In the light of our experimental observations which agree well with clinical experience, we dare to believe that when the dietaries of expectant mothers are planned to include liberal quantities of inorganic constituents in their proper proportions, a long step will have been taken toward the eradication of this disease which has baffled the medical profession for so many generations. If this theory is proven true, rickets of the future will be the responsibility of the obstetrician rather than the pediatrician.

ROLLA G. KARSHNER, M. D. (1136 West Sixth Street, Los Angeles)—As Doctor Chappel has justly stated, the x-ray is distinctly valuable in the recognition of rickets. However, a number of conditions must be excluded. It occurs most commonly at an age when other bone dystrophies, likewise manifesting multiple and symmetrical lesions, make their appearance. The differentiation is made by directing attention to the epiphyseal line. In rickets this is profoundly disturbed. It becomes softened and spreads, often with a roughly saw-tooth appearance. The end of the diaphysis resembles an inverted saucer, most marked in those joints where the mechanical forces are in line with the shafts. The epiphysis itself is not disturbed except possibly as a result of generalized atrophy. Often the lime salts are slightly condensed at the epiphyseal line. There is swelling of the periarticular soft tissues. The above changes cause limitation of motion and a general atrophy of the bones with softening, bending, and multiple fractures often resulting from non-use and impaired nutrition. Rarely there is periostitis in the acute stage. The chest will show the rosary even when it is not demonstrable clinically, and in severe cases one may see atelectatic strips in the lung beneath the costochondral junctions. With proper treatment, calcium is deposited in the periosteum and the cartilagenous epiphyses, in the latter case not as a direct continuation of the bone, but somewhat separated so that the picture may be confused with scurvy. In healed cases one often notes thickening of the cortex; for example, notably along the inner border of the shaft of the tibia and transverse lines of density in the ends of the shafts. The epiphyses remain expanded.

In chondrodystrophy the bones are shortened, dense; fractures are rare. The ridges for muscular attachments are enlarged. The joints are normal. The hands, feet, and changes in the base of the skull are unique. The shafts of the bones expand abruptly at the epiphyses, and ossification is deficient, irregular, often with localized overgrowths. The changes in cretinism are somewhat similar to those of chondrodystrophy.

Hereditary deforming chondrodysplasia (multiple oxostoses) often involves the epiphyses much as chondrodystrophy, the differential point being the formation of tumors of various density arising from the cortex, most frequently juxtaepiphyseal, and pointing away from the epiphysis. Osteopsathyrosis presents markedly diminished bone density, deformities, fractures, but no changes in the joints or epiphyses. In congenital lues in infants the destruction is in the epiphyses, principally, however, sharply circumscribed on the diaphyseal side at the junction of the periosteum and epiphyseal cartilage. There is usually periostitis, but no saucer-like expansion of the epiphyses. Scurvy presents intact joints and epiphyses with the destructive Trümmer zone simulating a second epiphyseal line, and there are frequently subperiosteal hemorrhages. Nutritional disturbances and arthritis (Still's disease) do not involve the epiphyseal lines.

WILLIAM SIDNEY BOWERS, M.D. (1136 West Sixth Street, Los Angeles)—In recent years preventive medicine, particularly in pediatrics, is rapidly advancing. I am very glad to see Doctor Chappel stress the point of an early diagnosis and treatment in rickets before marked deformity has occurred. In the more advanced cases, the parents frequently diagnose this disease, but then such marked deformity has occurred that, although proper curative and orthopedic treatment is instituted, it is almost impossible to overcome the deformity.

I do not agree that we have not advanced in our knowledge of the etiology of rickets, for in the past five

years we have acquired considerable valuable data concerning this disease. The outstanding factors in the etiology are both dietetic and environmental. The determining factors in the diet are not entirely settled, but depend upon certain salt combinations—hydrogen ion concentration, and the presence or absence of an unknown constituent closely associated with fat soluble A vitamin. The factor of environment involved is the presence or absence of radiant energy.

The seemingly well child mentioned as developing rickets on a well-balanced diet, with sunshine, fresh air, and exercise, would not have developed it, I feel sure, had cod-liver oil, or even radiant energy in some form, been properly administered, or possibly egg-yolk. Now, while this preventive treatment need not be instituted with all infants, certainly the pediatricists and others practicing with infants should recognize certain conditions which predispose to rickets, namely, prematurity, pigmented skin, and extra-rapid growth. In these cases proper preventive treatment against rickets should be instituted.

Regarding the early recognition of rickets, I believe it can be diagnosed clinically in the majority of cases as early, and in some cases earlier, than with the roentgenogram. In other words, a negative roentgenogram does not rule out early rickets, and while the roentgenogram is a valuable aid in the diagnosis in many cases, it is not a necessity in all cases. The blood inorganic phosphate findings are quite characteristic in rickets, but not pathognomonic. Many recent investigators have emphasized the difficulty of establishing a diagnosis of rickets in the early stages from the clinical findings, but certainly if the findings warrant a probable diagnosis of rickets, it is better in this disease to err on the safe side and treat the case for rickets, for this treatment in itself is harmless.

The early signs of rickets are cranio-tabes, differentiating this from congenital ossification; rachitic rosary, ruling out scorbutic rosary, and cranial bossing, ruling out luetic bossing. I believe such findings as flabby musculature, wide fontanel with surrounding softening, and delayed dentition, when occurring in conjunction with some of the above mentioned signs, are of aid in the diagnosis, but existing alone are of little value. Enlarged epiphyses, Harrison's groove, bent limbs, "pot-belly," delayed closing of fontanel, occur relatively late in the disease. Head-sweating, anemia, and palpable spleen are not dependable findings.

The orthopedic treatment as outlined by Chappel would seem conservative, and I would expect it to bring results.

H. H. MARKEL, M.D. (380 Post Street, San Francisco)—Doctor Chappel's paper is of peculiar interest to me, for I have recently had a family of three children under my care for knock-knee. The first child, a boy of 8, was so far advanced that an osteotomy of the femora was necessary. The second, a girl, needed casts only, which were later wedged on the outer side, and then wore braces. The youngest, a girl of 3, is fat and rosy and apparently well, but if she continues to be fed as the other children were she will develop a knock-knee. But I have given her mother a shotgun prescription of cod-liver oil, fresh meat and vegetables, and *sunshine*, and I expect to prevent her deformity from appearing. Another thing I have noticed is that all children who come to me for bow-legs or *knock-knees*, have *not had fresh meat to eat*. Even with a full set of teeth, the mothers all seem to fear giving them meat—why I cannot tell, except possibly a fear of choking. Recently, too, I have had consultations with Dr. Martha Jones regarding these early rachitic cases. She has assured me that her experiments have shown that deficiency of calcium metabolism in the mother in the late stages of pregnancy is responsible for rachitic changes in the young. This is manifest in the well-known saying, "For every child a tooth." I am sure that there are many more cases of rickets in California than we have formerly considered, even though we have an abundance of sunshine and fresh fruits during nearly the whole year—but we probably do not make the best possible use of them.

Physician (to rich patient)—You're all run down. I suggest that you lay off golf for a while and get a good rest at your office.—Life.

SOME IMPORTANT POINTS IN THE RAPID HEALING, COMPLETE RESTITUTION OF FUNCTION, AND LOW MORTALITY IN SUPRAPUBIC PROSTATECTOMY CASES.

By HERBERT A. ROSENKRANZ, M. D., *Los Angeles*
(From the Department of Urology, Los Angeles
General Hospital)

Since urologists have, during the past ten years, built up a system of procedure which has made possible the restoration of health and function to the patient and the adding of years of comfort to his life, so that he need no longer be subjected to a life of suffering coupled with impaired physical and mental activity and in many cases early death, I hold it to be our duty to correct any mistaken impression that may exist among some of the laity, that prostatectomy is a dangerous operation and leaves the patient impotent, a dribbler, or with some unhappy sequelae; because the simple, shockless procedure of suprapubic prostatectomy may be unhesitatingly recommended as a cure for this condition.

DISCUSSION by Louis Clive Jacobs, *San Francisco*; Robert V. Day, *Los Angeles*; Jay J. Crane, *Los Angeles*.

PREPARATORY TREATMENT—In one of my first papers on prostatectomy, read about nine years ago, I stated that the most important part of the prostatectomy was the preparation, and my experience since that time has confirmed that belief.

PROGNOSIS—A markedly emaciated patient is a poor risk, regardless of otherwise brilliant findings. I also draw the line on imbeciles, the bedridden and advanced tabetics. I believe that in the past we have been too narrow in our determination of fit surgical risks. We have been inclined to place our whole trust in the kidney function and blood chemistry findings, with a tendency to ignore a weakened myocardium, general debility, malaise, blood pressure, infectious and other complications, such as fistula in ano, carbuncle, bed sores, obesity with broken heart compensation and pyelonephritis. Such conditions must be relieved before operation. I do not operate upon a patient until or unless he is feeling good. I have not found high blood pressure up to 250 systolic to be a contra-indication to operation. A patient with a very low pressure should be carefully checked up. His vitality is low.

NURSING—The selection of competent, trustworthy nurses, is all important, not merely from the standpoint of morbidity, but from that of mortality as well. The urologist should provide himself with a sufficiently large list of reliable nurses of good character, or all of his good work may be for naught.

DIAGNOSIS—The more common mistaken diagnoses that have been referred to me for prostatectomy have been stricture, contracture of the bladder neck, acute and chronic prostatitis, tuberculosis of the bladder, bladder calculus, diverticulitis. Combination of prostatic tumor and stricture or prostatitis I have found to be not so rare, and unless these coincident conditions are first relieved the prostatectomy will either not cure the patient, or convalescence will be more or less indefinitely postponed.

CONSULTATION—I have found it a most excellent arrangement to have associated from the beginning of the treatment an internist. His counsel in a number of cases has proved invaluable.

GASTRO-INTESTINAL—Hygiene is of prime im-

portance. I have had several cases of fecal impaction, resulting from the extreme protrusion of the tumor into the rectum. In these cases the enema fluid will frequently not return, but must be syphoned away. To relieve these cases I employ oil enemas, flaxseed tea, castor oil, cascara, and other laxatives and cathartics. Unless the bowel has been thoroughly cleansed and regulated, a stormy convalescence is the rule. A high saline enema is frequently given daily. Cathartics are administered before breakfast, so that the patient's sleep will not be troubled. Charcoal tablets are administered thrice daily. Abdominal massage, walking, and easy physical exercises are prescribed.

HAEMOSTATIC—(1) Calcium lactate gr. XX t. i. d. for three days preceding the prostatectomy.

(2) Two cups of fruit gelatin daily for three days prior to operation.

(3) Fibrogen—one or two ampoules subcutaneously the night before operation. Two ampoules one hour before operation. I also employ fibrogen to adjust coagulation time of the blood when necessary.

(4) Spinal anesthesia. It lowers blood pressure and delays muscular contraction of the traumatized tissues.

CARDIAC—Endocarditis, provided compensation can be established, is by no means a contra-indication to operation. A myocardial weakness, however, that does not readily respond to digitalization is a treacherous condition. It is better for such a patient to lead a catheter life, or at any rate to dispense with operation. *Digitalization*: I utilize digalen one ampoule intravenously t. i. d., or digifoline one ampoule subcutaneously t. i. d.

TONICS—Aside from the old standard, elixir of iron, quinine and strychnine, I have achieved good results with cod-liver oil preparations in building up the patient's health, and I believe also in specifically increasing his resistance to infection and other complications that the asthenic may be exposed to. Containing as it does 400 times as many vitamins as any other preparation, is it not probable that we have too often failed to bear in mind the efficacy of this drug? Calcium chloride is a cell tonic and eliminant, and I frequently administer three grains intravenously once daily.

GENITO-URINARY PREPARATION—A bladder that contains more than 200 cc. of residual urine should be emptied fractionally, and an indwelling catheter inserted. Daily instillations of argyrol or irrigations of silver nitrate, mercurchrome, or boric acid are administered, according to the degree of infection and the tolerance of the patient, the object being to reduce congestion, infection, and sensitiveness of the bladder, and particularly of the prostate and trigonal region, in order to lessen the kidney reflex that occurs at the time of prostatectomy. *Fluids* are only moderately increased in quantity, since I have found it necessary to safeguard the myocardium as well as the kidneys. *Cystoscopy*: This procedure should be preceded by administration of acid sodium phosphate and hexamethylenamin for several days, and these drugs should not be left out of consideration in the preparatory and after treatment of those patients predisposed to pyelonephritis. If practicable,

an indwelling catheter is utilized for several days preceding suprapubic cystotomy.

ANESTHETIC—I prefer gas oxygen for the first stage, and spinal for the second stage. Some patients demand to be put to sleep for the second stage, and to these I administer gas oxygen or, if the prostate is very deeply situated, ether. I object to local anesthesia because it tears tissues, thereby reducing their resistance to infection. I have never seen any untoward result due to gas-oxygen anesthesia. Parasacral anesthesia is not adequate for suprapubic work. I have found a spinal anesthetic of from one and three-quarter to two and one-half grains of novocain, ideal in all cases except those with low blood pressure. To the latter named I give a general anesthetic. Spinal anesthesia justly deserves the high place that it holds in this operation, because it prevents hemorrhage by lowering blood pressure and by allowing the prostatic cavity and the muscles surrounding it to remain at rest for some hours following the operation. By this means it also minimizes what little pain might otherwise ensue; and also blocks any immediate renal reflex, and I believe minimizes shock by blocking many other reflexes. The patient partakes of eggnog every three hours following the operation, instead of suffering from nausea and vomiting, as may be the case after a general anesthetic. I once asked Mrs. Greer, head nurse in the urological department of the Los Angeles County Hospital, to what she attributed the excellent results that we were having with our prostatectomy cases. Her instant reply was: "Doctor, I feed my patients. I give them plenty of eggnog on the day of operation and thereafter." Some time ago I walked through the urological ward of our General Hospital and noticed a patient upon whom I had performed a prostatectomy three hours previously under spinal anesthesia. He was sitting up in bed, with a writing board on his lap and a pencil cocked back of his ear. He was folding a letter which he had just written, setting forth the happy outcome of his operation.

ONE-STAGE VERSUS TWO-STAGE—My results with the one-stage have been as good as with the two-stage in selected cases, and when I have taken care of the cases personally. The absolute indications for a two-stage operation I hold to be:

- (1) Bladder or kidney calculus.
- (2) Acute vesical retention.
- (3) A stubborn cystitis.
- (4) Intolerance to the indwelling catheter.
- (5) A prostatic tumor of enormous proportions.

In spite of the fact that my results and mortality with the one-stage operation have compared most favorably with those of the two-stage, and, although a patient occasionally dies after the preliminary cystotomy, an exitus that would have been illogically charged to the one-stage operation had prostatectomy been performed at that time, I am nevertheless leaning more to the two-stage operation for the following named reasons:

- (1) A more complete bladder drainage is obtained than by urethral catheter drainage.
- (2) Less shock at the second operation.
- (3) There is not so much likelihood of perivesi-

cal infection, although I think that all of us have encountered malignant infections that persisted in boring pockets following even the two-stage operation.

(4) Less congestion and swelling of prostate, due to absence of the irritating indwelling catheter. Less edema of bladder neck.

(5) No absorption of the occasionally very toxic urethral pus caused by the irritation of the catheter.

(6) Bladder is kept freer from infection.

(7) Less likelihood of epididymitis.

OPERATIVE—After the patient has been thoroughly prepared and stabilized, the important consideration is to remove the prostate with as little shock as possible. For this the suprapubic operation is ideal, in that it rarely requires more than seven minutes for its performance.

OPERATION—FIRST STAGE—After exploring for stones in bladder or in diverticulæ and for papillomata, etc., a sufficiently stiff one-half inch rubber drainage tube is introduced into the upper posterior wall of the bladder, and tightly secured by a purse string or other suture. The prevesical fascia is brought together with No. 1 continuous gut. In peeling up the peritoneum, care is taken not to separate the bladder from its anterior attachments to pubis and muscle. This requires some gentleness, but is worth the effort. Rectus fascia is sutured with *interrupted* No. 3 catgut to prevent hernia. Fascia and skin are sewn loosely around tube to insure free drainage of serum. Pezzer catheters get pinched, kink and tear, and their caliber is not large enough. I have never used them to any extent.

OPERATION—SECOND STAGE—The entire surface of the suprapubic opening is sharply curetted. I stretch the incision very little on account of the possibility of tearing the peritoneum. The incision is continued downward and if necessary a rectus muscle with its sheath is cut transversely, each to be carefully sutured with interrupted sutures later. After enucleation the rim of the bladder incision is freed from the rectus muscles and tightly sutured around a one-half-inch rubber tube, after which the muscle and skin are sutured separately. It is necessary to free the skin from its deeper adhesions before suturing it with the marine stitch. It is to this thorough method of suturing that I attribute the rapid healing and dry condition of the patient during convalescence. During the past two years several nurses have remarked that my cases remain clean and dry, "just like abdominal cases." *Hemostasis*: During the past ten years I have not seen fit to modify my procedure of tightly packing the entire bladder of those rare cases that bleed on the table, or of those cases that have tumors of such large size that they are potential bleeders and likely to bleed later on, even though they remain dry on the table. The pack is removed fractionally every three hours during twelve to eighteen hours. Of course, there is no room for a tube when the bladder is tightly packed. When the pack is removed, an indwelling catheter is inserted in the urethra. Pituitrin, in addition to being supportive, is also hemostatic.

POST-OPERATIVE TREATMENT—Frequent sips of

hot water, later water of room temperature. Pituitrin every four to six hours for several days. Digifoline thrice daily when that support is indicated. Morphine grains one-eighth plus atropine grains one-three hundredth if there is pain. Eggnog every three hours. Sitting position a few hours after operation, with occasional changes of position. *Enemas* and colon tube as soon as there are any gas pains. An enema is soothing and affords great relief from the pressure of gas-filled bowels upon the sore bladder. *Oliguria*: One thousand cc. intravenously of soda and glucose solution daily. Diuretin twenty grains thrice daily. The administration of 2000 to 3000 cc. of intravenous solution daily to elderly individuals will, I am sure, in a fair percentage of cases break down myocardial compensation, as will also the administration of a large amount of fluid by mouth. Myocardial weakening is the most treacherous complication that can occur, and the surgeon who can keep the myocardium in a stabilized condition will have the lowest mortality. *Pernicious hiccough* is stopped by hypodermics of morphine and atropine every two hours. *Hemorrhage*: A 5 per cent mixture of aluminum acetate in water is the most effective local injection. If this does not control, the bladder must be packed under an anesthetic. I have never found it necessary to pack a bladder post-operatively. Lately I have found fibrogen a valuable remedy. *Irrigations*: I frequently do not irrigate the bladder till the second or third day following operation, and then only with boric acid in the morning, supplemented by an instillation of 5 per cent argyrol in the evening. Instead of every day disturbing the sore prostatic pouch, which is doing its best to get along, I affect a compromise by having the nurse irrigate the drainage tube and bottle instead twice daily with mercuric chloride solution. This, together with keeping the suprapubic tube and incision carefully cleansed with alcohol does, I am sure, contribute to the freedom of infection which many of my patients have enjoyed. Cleanliness is next to Godliness, and its rigid application in these cases must be insisted upon to the same degree in which it is applied by the orthopedic surgeon. *Infection*: Infection in the prevesical space yields to swabbing with tincture of iodine and, if necessary, frequent instillations of mercurochrome 1 per cent. Infection of the prostatic pouch is treated by irrigations of silver nitrate, acriflavine, and instillations of 10 per cent argyrol. Pyelonephritis is treated by the usual methods and intravenously with 20 cc. of 1 per cent mercurochrome solution. My experience with mercurochrome intravenously in acute infections has caused me to regard it as one of the most valuable drugs that have been added to our list in a long time. It has been some years since I have had a sloughing wound in private practice, even in those cases complicated by stone. Careful operative technic, aseptic and antiseptic measures are responsible for this. It has been my observation that it is the germs that are brought in from the outside, and not those already there that do the damage. *Healing*: The small sharp curette is an invaluable instrument for removing redundant tissue and for freshening the suprapubic opening. Its discriminating use is an important factor in rapid healing in some cases.

Necrotic fat or other tissue should be promptly removed with a long thumb forceps. *Fever* is most commonly due to constipation and less commonly to infection.

GOING HOME too soon causes epididymitis, due to the many added strains that the patient is tempted to assume as soon as he arrives there. A few added days of sitting in a chair, with but little walking around the hospital, is the best for the patient. As soon as he begins to walk, he should wear a scrotal suspensory and continue to do so for several months. Patients with high blood pressure must be cautioned against overeating and overwork. Their blood pressure should be watched and controlled.

PNEUMONIAS, although rare, I have seen occur almost as frequently in those who were undergoing preparatory treatment as in those who had been operated upon. I have seen almost as many patients develop pneumonia following spinal as following ether or gas anesthesia. I believe that an infected environment, plus hypostatic congestion, play a far more important role than does the irritation of an ether anesthetic, although I do attribute one of my exits to this cause.

RESULTS—I have had one case of impotence following prostatectomy. After one year, however, the potency in this 67-year-old patient had improved to a condition better than that of the average man of his age. Recently I had a case of troublesome paresis of the bowel that persisted for four days following a spinal anesthetic. Since this condition, however, may occur after any pelvic operation, regardless of the type of anesthetic used, it would be unfair to discriminate against spinal anesthesia on this account. Dr. Crane at the Los Angeles County Hospital, in checking up on the residual urine of eighty-six patients before they left the hospital, found that 3 per cent had residual urine of as much as three ounces, 10 per cent about one ounce, and the remaining 87 per cent had none at all.

My first Los Angeles prostatectomy, performed almost nine years ago, is still living and in good health.

CANCER—Some four years ago I inaugurated the procedure of partial suprapubic prostatectomy for cancer of the prostate. I reported two cases. Inquiry today revealed that they are both in fair shape. One of them was operated upon four and one-half years ago, and is under the care of Dr. Granville MacGowan; the other was operated upon five and one-half years ago. Some time ago, having had the co-operation of Dr. Percy in some work on cancer of the bladder, I was impressed with the probable good results that could be achieved by the cautery method in cancer of the prostate. I have employed the method in several cases lately, and am inclined to believe that, by burning out the whole prostatic mass with the cautery and supplementing this by radium later on, we have the best procedure for attacking this condition. The operation is tedious, requiring sometimes two hours, the technic being to keep on burning until the *soft* surrounding tissues are felt.

MORTALITY—As has been so aptly stated: "Put a hundred men, varying from 60 to 95 years of age,

to bed for a few weeks and it need occasion no surprise if one or several of them die from something or other, even though no operation is performed." Taking this fact into consideration, urologists must congratulate themselves all the more for the very low mortality that they have been able to maintain in suprapubic prostatectomy—ranging from one-fourth of 1 per cent to 5 per cent. During a six months' service at the Los Angeles County Hospital a year and a half ago, I operated upon thirty-three unselected cases, some of whom appeared to be rather poor risks, but all of them recovered, a result due largely to the alertness and painstaking care of Dr. J. J. Crane, resident urologist. Gardner has reported 240 consecutive suprapubic prostatectomies, without a death. I have not had a death in private practice in about three and one-half years. Since urologists have, during the past ten years, built up a system of procedure which has made possible the restoration of health and function to the patient and the adding of years of comfort to his life so that he need no longer be subjected to a life of suffering, coupled with impaired physical and mental activity and, in many cases, early death, I hold it to be our duty to correct any mistaken impression that may exist among some of the laity that prostatectomy is a dangerous operation and leaves the patient impotent, a dribbler, or with some unhappy sequelae; because the simple, shockless procedure of suprapubic prostatectomy may be unhesitatingly recommended as a cure for this condition.

610 South Broadway.

DISCUSSION

LOUIS CLIVE JACOBS, M. D. (Flood Building, San Francisco)—Dr. Rosenkranz's paper is a valuable contribution to modern surgery of the prostate. It deals with a large number of procedures which are essential to the complete recovery of the patient. For when all is said and done, an operation for the removal of the prostate is not a therapeutic success unless the candidate is in good physical condition, say, three months following the prostatectomy. To achieve this result, is the ambition of every urologist. Hence, we see the importance of the preliminary treatment and preliminary investigations.

I make a routine cystoscopic examination, roentgenological examination, complete blood examinations, with estimation of the blood urea and a urine examination in every case. Blood creatinin is a valuable index of the kidney function, but the laboratory estimation of the same is unreliable on account of the variation of the colorimetric reading with a standard that is unstable.

In regard to the fractional emptying of the bladder and the insertion of the indwelling catheter, I am heartily in accord with what the doctor states. Recently, I saw a patient in consultation, from whom a very large amount of urine had been withdrawn at the first catheterization. This was followed by a hemorrhage, and shortly afterward the patient died from anemia of the heart muscle.

There has been a noticeable decrease in the mortality from prostatectomy in late years, especially in urological services under the supervision of genito-urinary surgeons, such as Dr. Rosenkranz. This is due, I believe, to the determination of the surgical risk and the minute and painstaking attention and care given to the pre-operative and post-operative phases of the surgery.

As regards the choice of the one or two-stage operation, I am a strong advocate of the single-stage procedure. Usually it can be advantageously performed, though there are some exceptions where the two-stage method should be done. The suprapubic approach reduces the post-operative complications, such as fistulae

and impotence, to a minimum, and is, therefore, the procedure to be preferred. There should be a minimum of time consumed in the actual removal of the prostate, and in my experience the anesthetic of choice is "gas and oxygen." My patients are usually conscious within five minutes of the tying of the last suture. Sodium citrate solution should be administered per rectum immediately, and fluids in moderate quantities fed through the mouth. As a safeguard against embolism, nothing should be administered per rectum after twenty-four hours have elapsed.

The following points in the doctor's operative technic are of prime importance and, to my mind, cannot be too forcefully mentioned:

Not to separate the bladder from its anterior attachments.

Incise into the high part of the bladder.

The doctor's methods for controlling hemorrhage and for draining the bladder are excellent. I pack all my cases with three-inch gauze, and allow it to remain to the third day. Occasionally, I place a tube alongside of the gauze. I never insert a catheter into the urethra until at least ten days have elapsed, and sometimes not until three weeks. If I encounter severe hemorrhage during the operation, I aspirate with the air-suction aspirator inserted into the wound and, with the bladder wall retracted, suture the capsule of the prostate.

The pharmaceutical preparations enumerated by Dr. Rosenkranz are all of great assistance in sustaining the patient, and should be used wherever indicated. Just two more drugs, I believe, deserve mention, and those are camphorated oil and caffeine.

As regards residual urine, following the removal of the prostate, this is almost always due to tags of prostatic capsule or small portions of adenomatous tissue lying in the posterior urethra, and it would be necessary in these cases to fulgurate them through the cysto-urethroscope.

ROBERT V. DAY, M. D. (412 West Sixth Street, Los Angeles)—Doctor Rosenkranz has given us a very complete and most excellent discussion of prostatism and its cure. Everyone must agree with him that the preparation of the patient is the most important part. In the bad risk I prefer the two-stage operation. With the younger patients—say under 70—without evidence of serious cardio-circulatory disturbance or irreparable damage to the kidneys by reason of the long-continued back-pressure, the one-stage operation is probably the one of choice. We control bleeding in the one-stage operation by suturing the posterior lip of the bladder neck, followed by the use of the Pilcher bag. With the two-stage operation, however, it is difficult to suture the bladder neck, and we rely entirely on the Pilcher bag. The bag causes much less distress than gauze packing.

In the main, I agree most heartily with Doctor Rosenkranz. However, I am opposed to indiscriminate medication, such as bitter iron tonics, diuretin, urotropin, calcium chloride, etc., because they are apt to upset the patient's digestive apparatus. (Digitalization is frequently necessary.) Iron and vitamins are so abundantly present in spinach, egg-yolks, and milk that such medication would seem superfluous. Water, lemonade, fruit juices, and buttermilk are the best urinary antiseptics and diuretics. Enemas often cause tenesmus and are occasionally responsible for the dislodging of a clot with resulting pulmonary embolism. Unless the patient is in great shock I never give intravenous salt, glucose, or sodium bicarbonate, for the reason that most of these men have emphysema and chronic bronchitis, and large amounts of these substances perhaps favor pneumonia. Sodium bicarbonate, after sterilization by heat, contains a considerable amount of sodium carbonate, and almost always causes a severe chill or reaction. Hemostatics are not necessary if the bleeding is properly controlled by suture and hemostatic bag.

Spinal anesthesia is invaluable in a majority of suprapubic prostatectomies. It got a bad name when the anesthetic agent used was stovain—a very toxic and dangerous drug for spinal anesthesia. We have records of over 5500 cases of spinal anesthesia used in the Los Angeles General Hospital since 1910 on the urologic and

rectal services, and many hundreds prior to 1910. The anesthetic agents in this series were tropacocain and novocain, either one of which is satisfactory.

JAY J. CRANE, M. D. (Westlake Professional Building, Los Angeles)—Dr. Rosenkranz's paper is very complete. He has dealt with all the different points very thoroughly that lead to a low mortality, and the complete restitution of the patient operated upon for prostatism. Dr. Rosenkranz has had a wide experience, and the results he has had I know have been excellent, for I have seen many of his patients cured and out of the hospital in four weeks, and I am glad to have him put down in writing the things he pays particular attention to, so that we can follow his suggestions.

It is routine at the Los Angeles General Hospital to do a roentgenological examination of the urinary tract, a complete blood chemistry, a complete urinalysis, kidney efficiency test with phenolsulphonephthalein and a bladder cystoscopic, besides the routine physical examination, which includes the blood pressure on every candidate for a prostatectomy. In following this procedure, it is not infrequent that we pick up symptomless renal calculi, diverticuli, bladder calculi, strictures, and cancer, any one of which might be overlooked, were this routine not followed, thereby changing a good prognosis to a more doubtful one. As Dr. Rosenkranz has said, one cannot depend solely upon laboratory test. The patient must feel good, and have a good moist tongue, as well as a good kidney function and blood chemistry.

In spite of the fact that many brilliant results have been obtained with the one-stage suprapubic prostatectomy, I am in favor of the more conservative two-stage method. It has been my observation that the patients operated upon by the two-stage method have, as a rule, as short a convalescing period as those that have the one-stage operation. It is a fact that most of the poorer risks receive the two-stage method, so why not conserve the strength of the patient in better condition also, for he will usually make a much better convalescence. A vasectomy done at the time of the suprapubic cystotomy will eliminate the embarrassment of an epididymitis when the catheter is replaced in the urethra. I have had patients tell me that they suffer more with an epididymitis than with a prostatectomy. Just recently it became necessary for me to do an orchectomy one month after the patient had left the hospital and had a normally functioning bladder. The patient developed an epididymitis, which broke down and had to be opened twice. Abscesses continued to form until the sloughing epididymis and testicle were removed. This would not have happened had a vasectomy been performed at the time of the suprapubic cystotomy.

Dr. Rosenkranz's method of controlling hemorrhages by packing the prostatic cavity and bladder at the time of operation is absolute. As Dr. R. V. Day has said many times, after packing the bladder you can go home and sleep, without fear of hemorrhage. It is true that this procedure is painful, but unless the wound is sutured too tightly I do not believe it is any more painful to the patient when the pack is removed than when a bag used for the same purpose is removed, and it does control the hemorrhage. There is no question about that. A small pack in the prostatic cavity, unless held by a sponge holder strapped by adhesive to the belly wall, or by a catheter through the urethra, is, I believe, dangerous, for a hemorrhage of any moment will usually carry the pack to the fundus to obstruct the outflow of urine and blood through the incision, allowing the bladder to fill up with blood clots. Dr. Rosenkranz's rule of packing the bladder of all cases that have very large prostates, and of those who show a tendency to bleed at the time of the operation, is a very safe and conservative method.

I am of the opinion that the spinal anesthetic is by far the safest anesthesia for both stages. I have found many patients who are more afraid of being put to sleep than they were of the operation, and who would submit readily to the operation if they could escape a general anesthetic. I believe the majority of cases will make a better convalescence following spinal than following any other form of anesthesia.

I have found that the tube put in the wound for drainage at first when a pack is not used should be large.

Nothing under one-half inch in diameter should be considered. When the pack is removed, such a tube should be put in for a few days. As soon as all gross evidences of hemorrhage have subsided, the two-inch tube may be readily replaced by a Pezzer catheter, which will not retard healing of the wound during the following ten days, allowing the prostatic cavity to heal unmolested. At the end of ten days a catheter can safely be inserted through the urethra, allowing the suprapubic wound to close.

DOCTOR ROSENKRANZ (closing)—The reason that I have stressed close observation and safeguarding of the myocardium is that there has not been evolved a satisfactory measurement of cardiac reserve. The spirometer does at times, however, seem to be of some use in checking up this most important factor. I take daily blood pressure readings post-operatively, and keep the pressure at a satisfactory level with pituitrin and strychnine.

As regards mercurochrome irrigations, it is well to bear in mind that mercurochrome is mercury, the daily administration of which may cause a local sclerosis, so that I would not recommend it for continued daily usage.

The reason why some cancers are of very slow growth or have their growth arrested following their partial removal, or why some of them even get well spontaneously following such removal, is not known. I have discussed the subject with Dr. Percy, and he has noticed that occasionally patients have gotten well following partial removal with either the knife or the cautery.

Dr. Day and Dr. Jacobs have advocated the suture of the capsule in cases of bleeding. About three years ago, on inserting my finger through the suprapubic incision into the prostatic urethra prior to enucleation, I felt a large artery pulsating in the urethra. The artery was almost one-half centimeter in diameter, and was palpated by Dr. Crane and the resident urologist of the General Hospital. I expected a lively hemorrhage, and got it. It was, however, immediately and completely controlled with the bladder pack. I have never found it necessary to resort to any other expedient. The pack does occasionally cause some pain. This can, however, be satisfactorily controlled with morphine, and I have had some patients in whom a tight bladder pack has not caused pain. I learned the bladder pack from Colonel Freyer. During the International Congress of Surgeons in London in 1914, I saw him remove the two largest prostates that I have ever seen. The blood spurted and welled out of the suprapubic wound in each case, as was to be expected. He immediately packed the entire bladder in each case with a five-inch roll, which completely and immediately checked the bleeding. I shall always remember his technic as one of the most valuable points that I have ever picked up, and I believe that, in time to come, this method of packing will be used with increasing frequency. It is safe, sure, simple and immediate in action.

I am glad that Dr. Jacobs stresses preliminary roentgenological, blood chemical and cystoscopic examinations, for, although the laboratory sometimes misleads us, it does at times give us a danger signal that would otherwise have been withheld.

As regards the danger of embolism following an enema, I may add that I use a soft catheter and that nothing has afforded my patients greater relief after operation than has the enema for removal of gas. Colon tubes I have found to be absolutely inadequate. I believe that many cases of so-called embolism have been something else. I have known of patients to pass out while straining at stool, and while sitting up in bed eating a meal. Both cases were attributed to embolism, but there was no post mortem. I have had one case of infectious embolism that recovered. Ten years ago I removed a very large prostate, together with a large calculus from a patient who had had a large prostate removed perineally some years previously. His bladder was very badly infected. About three days after operation I found him with a paralysis of the tongue, paralysis of pupils and one side of the face, etc. He also had a putrid and severe pneumonia. It was a case of brain and pulmonary embolism combined. This patient had a wonderful constitution, and is living and well today.

As Dr. Daly has suggested, we must use discrimina-

tion in medication. I have used cod-liver oil, properly emulsified, so as to render it palatable, and I am sure that it has built up the health of certain patients.

I wish to thank Dr. Jacobs, Dr. Day, Dr. Stevens, and Dr. Crane for their good discussions.

Spinal Drainage: Value in the Treatment of Early Poliomyelitis—The data gathered by J. C. Montgomery and W. C. C. Cole, Detroit (Journal A. M. A.), in twenty-six cases of poliomyelitis strongly suggest a possible beneficial effect on the outcome of the disease to be derived from early and repeated subarachnoid drainage. Vomiting was noted as the predominating initial symptom. Fever was the symptom complained of in thirteen cases. Headache was noted relatively rarely, although at some time during the course of the disease it was present in 70 per cent. Pain was noted in only 54 per cent. Fever occurred in every instance, and vomiting was noted in 60 per cent of the cases. Some redness or injection of the tonsils or pharynx was noted in practically every instance and persisted from one to two weeks after the onset of the illness. This was a matter of varying intensity; in some cases there was only a mild redness and in others a severe angina, the hyperemic area extending up into the nasopharynx, where a grayish-white exudate was almost invariably seen. Hyperesthesia was noted in every instance, although it, too, varied considerably in its intensity. Irritability was observed in about one-half the cases, although it was somewhat more constantly present in the early ones. Of the clinical signs, aside from hyperesthesia and pharyngitis, those most constantly present were neck rigidity and resistance to anterior flexion of the spine, these signs being found in 92 per cent of all cases, or in all but two. The reflexes were most unproductive of information in early cases. They were found normal, exaggerated, sluggish and, absent. The most that could be learned from them was that only in rare instances were they normal, and in one or two instances a difference between the two sides was of some help in arriving at a diagnosis. In two cases erythema of the face and neck was noted, and in one instance a definite punctate scarlatiniform eruption was present over the chest and back. This rash was so suggestive of scarlet fever that such a diagnosis was held probable, particularly in view of the severe angina that was present, and the absence of meningeal irritation. It was only when paralysis occurred that the true nature of the illness was recognized. Estimates of spinal fluid pressure were based on experience regarding rate of flow. While the pressure apparently varied in its intensity, nevertheless it was definitely increased in every instance except two, and these were beyond the acute stage. Similarly, the amount of fluid was increased in every instance except one. The degree of pleocytosis varied from 10 to 800. In some instances, when puncture was performed in the extremely early stage, practically no increase was detectable. It was a frequent experience that the cell count was higher on the second, third and fourth days of meningeal invasion than on the first day, even in the face of definite improvement symptomatically. This led to the conclusion that in those instances in which an extremely large amount of spinal fluid under great pressure is found, a cell count of 10 or 15 should be regarded, in a child at least, as a definite increase. It seems logical to assume that this low count at the first puncture may partially be explained on the basis of dilution. It has been the authors' practice, as soon as a diagnosis of poliomyelitis was suspected, to perform a lumbar puncture. If this showed definite increase in pressure, with or without a pleocytosis, it was repeated at twelve or twenty-four hour intervals until the pressure had definitely subsided. This usually occurred in about three or four punctures, and it was the usual experience that after pressure had once subsided it did not recur.

From the present study of the data supplied by the school districts it is estimated that about 12 per cent represents the amount of defective vision found among school children in the United States *under the present methods of examination*.—National Committee for the Prevention of Blindness.

Clinical Notes and Case Reports

ALLERGIC DERMATITIS

REPORT OF A CASE DUE TO MOHAIR

ALBERT H. ROWE, M. D., AND HOBART ROGERS, M. D.,
Oakland, California

Mrs. E. C. L., age 32, came to us May 26, 1925, complaining of an eczema which had for two years affected both forearms. The lesions when they first appeared had had a marked weeping tendency, but at this time were dry and scaly. Itching was a marked feature. The distribution of the lesions is shown in the accompanying unretouched photograph. At no time had lesions appeared on any other part of the body.

The condition had been treated previously by means of the lotions, ointments, and diets commonly prescribed by dermatologists. At one time the patient had for four months not allowed water to touch her forearms. The use of x-ray had served to control the weeping tendency, but had really benefitted the condition very little.

There was a positive history of allergy. The patient's mother had had hay-fever as a child. The patient her-

self had had hay-fever in her youth while a resident of Ohio. Her one child, 10 months old, had had eczematous lesions at the age of 3 months.

Food-testing by the cutaneous scratch method revealed only delayed reactions to raspberry, apricot, and banana, which reactions we felt were probably without significance. Tests with animal emanation proteins revealed immediate positive reactions to goose feathers, cattle hair, horse hair, dog hair, rabbit fur, sheep wool, and a marked reaction to goat hair.

The marked reaction to goat hair led to careful questioning as to contact with mohair. The patient then remembered that she had received a mohair upholstered overstuffed chair on January 25, 1923, that her eczema first appeared the first week of February following, and that the only period of improvement she had had was six weeks spent away from home.

Our instructions were to remove this chair from her home and to avoid allowing her skin to come in contact with any mohair, animal fur or wool. Improvement began about June 15 and continued uninterruptedly to the complete disappearance of the lesions, despite the fact that she had gone to the beach and was bathing in salt water every day. Her arms have now been entirely free

from lesions for one month. We do not deem it advisable to subject patients to a series of injections for desensitization when an exclusion therapy is so simple and so highly successful.

COMMENT

This case is illustrative of a very important group of dermatoses due to protein sensitization. Some few of these may perhaps be solved clinically, but in most, as in the present instance, the essential information will be withheld until the results of protein skin-testing have given the proper direction to the questioning. The patient is seldom able to associate his trouble with its cause. The only safe rule is to insist on complete and thorough protein skin-testing in all cases of unexplained or refractory dermatitis. If there is a positive history of allergy, skin testing is imperative. Positive reactions point the way to a specific therapy. In no field of medicine are results more spectacular or patients more grateful.

USEFUL APPLIANCES IN THE TREATMENT OF SOME COMMON INJURIES

By HARRY M. WEGEFORTH, M. D., AND
ARTHUR WEGEFORTH, M. D.,
San Diego

In treating patients with several fingers injured or infected, it is often difficult to redress them without causing considerable pain.

Having found that by using a perforated piece of celluloid

rounded off and covered with a strip of adhesive plaster. This will prevent irritation of the integument between the base of the injured finger and those adjoining it.

With this splint it is easy to apply a dressing that is both satisfactory to the patient and the surgeon, because all that is necessary, after the wound has been properly prepared, is to fold, in the form of a finger of a glove, the gauze on which ointment has been applied. If moist dressings are desired, the gauze, saturated with Dakin's solution, is applied around the finger so as not to interfere with the circulation of the blood. If continuous wet dressings are indicated, all that is necessary is for the patient to pour on the dressing, from time to time, the required amount of Dakin's solution, salt solution, or whatever solution is desired.

Among the many advantages of this method of treatment are:

1. That the splint can be easily removed and the finger exposed to the active rays of the sun or ultra-violet rays.
2. That it permits easy examination of the injured finger, without causing unnecessary pain.
3. That it lessens the danger of disturbing granulating tissue, as all that is necessary is to gently remove the wet dressings which do not adhere to the wound and replace them with new dressings, slipped over the end of the injured finger.
4. That the end of the celluloid splint projects about one-half an inch beyond the end of the finger, and thus affords protection from the danger of striking the injured part against objects.

Fig. 1—The use of celluloid in the treatment of ulcers of the external abdominal wall.

Fig. 2—Materials used in making a celluloid splint.

Fig. 3—Application of celluloid splint to finger.

lloid in treating ulcers of the abdominal wall we were able to prevent pressure on the wound and to avoid soiling of the bed clothes, we decided to apply this principle in the treatment of injuries to the fingers in order to overcome the annoying pain caused by the usual redressings and to give more satisfactory support in the case of fractures.

Ordinary celluloid, such as is used by automobile-top manufacturers, is satisfactory. Pieces are cut a little longer than the finger, overlapping about one-third of the distance. In order to avoid overheating and possible maceration of the tissues when saturated dressings are applied, the celluloid is perforated at several places by means of a harness punch.

In making a splint for the injured finger, a normal finger can be used for the purpose of shaping the celluloid. Allowances in size should be made for the type of dressings that is to be used.

The splint is retained in shape by means of pieces of adhesive plaster about one-quarter inch wide wound two or three times around the celluloid. In order to avoid the slipping of the splint, the proximal end may be perforated and the splint attached to the wrist by means of a piece of tape.

The sharp proximal ends of the splint should be

5. That in case of fracture, especially in compound fractures, the splint acts as a support for the fragments.

400 Granger Building.

A Workman's Compensation Bill Allowed—Recently a workman repairing automobiles was injured, and the foreman called a physician who was not employed by the insurance company that insured the automobile concern under the Workmen's Compensation Act. The physician rendered a bill to the employer of the patient who turned the bill over to the insurance company. The latter obtained a ruling from the Industrial Accident Commission, reducing the bill to about half its original amount. The question then arose as to whether the Industrial Accident Commission had the jurisdiction to reduce a physician's fees rendered unconditionally to the employer and at the employer's request. The municipal court of Boston rendered a decision in favor of the physician for the sum he claimed. The judge found that the physician was unconditionally employed by the employing corporation, which was liable for the full amount of the physician's bill.—*Journal Iowa Medical Society*.

It is more important for a doctor, no matter what character of medicine he practices, to have adequate malpractice coverage than it is to insure his automobile.

EDITORIALS

TWENTY-THREE YEARS

With this issue CALIFORNIA AND WESTERN MEDICINE completes twenty-three years in the field of medical journalism. They have been years of growth. Stunted at times for want of sustenance, but never to the extent of "malnutrition." Neither CALIFORNIA AND WESTERN MEDICINE nor any other publication can any more please all of its readers than can any physician please all of his patients. Neither is it possible to please all of the more than 4000 owners of the magazine. We are not stupid enough to make the attempt. What CALIFORNIA AND WESTERN MEDICINE does try to do is, to live up to a fair, square, definite policy fixed by the Council of the California Medical Association, and interpreted by the editor and his counselors. The result is pleasing to most of the owners. *Thousands* of encouraging letters during the past year testify to that fact. There have been a few of the other kind, and if there were not, we would feel quite certain we were not going anywhere in particular.

CALIFORNIA AND WESTERN MEDICINE is dangerously weak in one particular. It needs a substitute editor who should be warming up. But for the moment we are all here—a happy family.

Our best wishes for a Merry Christmas and a Happy New Year to our associates, owners, printers, readers, and even our enemies—God bless them.

BACK TO YOUR PERSONAL DOCTOR

The signs of the times seem to indicate rather definitely a growing movement to have less ballyhoo, fewer "health centers," clinics, and what not, directed by non-medical organizations and public health "officers," less "*officially directed personal health*" in general, and a return to the personal health doctor for personal health assistance and advice both in keeping well and getting well.

One of the most recent and significant bits of evidence supporting this prophecy is the wise attitude of the Federated Women's Clubs of Illinois. This great organization, instead of attempting to operate health centers, clinics, and generally practice medicine themselves, have established co-operative plans with the Illinois Medical Association and the Illinois Dental Society, by which the Women's Clubs will exert themselves to have all "pre-school" children examined *by their own family doctors and dentists*. The public health authorities furnish the blank forms.

"The plan involves," says the Illinois Medical Journal, editorially, "the emphasis of the personal responsibility of each member of the Federation for the children of her own household. It is asked merely that each of the 70,000 members see to it that one pre-school child, either of her own household or her neighbor's, or some child in her immediate community, is *taken to the family doctor and dentist for this complete examination*. Blanks for this purpose will be supplied by the State Depart-

ment of Health. Each member of the federated clubs in the ninety-three counties of Illinois, where there are active county medical societies, will be furnished a list of all members in good standing in the county medical society of her county. It will be made very clear that this examination must be handled by a doctor of medicine, and an explanation will be given in detail of what the single standard of medical education can guarantee as to the character and ability of the physician.

"This means a certain responsibility on the part of the county medical societies. They are asked to give friendly support to this effort to get children, apparently well, into their *own offices*."

That is as it should be. It is rendering a fine service in the way it should be rendered. As we have stated repeatedly, it is no more trouble to take a child to a doctor's office than to a clinic. The service is precisely as good and much more satisfactory because the patient goes to the doctor of his choice. It is cheaper to all parties, and particularly to those who pay *public bills*. It promotes the cause of public health as it should be promoted. It avoids the rush, hip hurrah and circus methods of health centers and the not insignificant exposures to infection in crowds of children as they are huddled together in most "free clinics." Above all, it allows the child to get acquainted with *his doctor* instead of the facets of a machine. There are enough doctors, and to spare. They are not all Emmet Holts, it is true, but they are the best we have, and a good average at that. Certainly, they are not inferior to those who do the work for "health centers." Mostly they are the same doctors.

With the co-operation of 70,000 club women of 700 clubs in Illinois, under the presidency of Mrs. George Thomas Palmer (wife of a physician) and under the immediate direction of Doctor Lena K. Sadler, Chairman of the Child Welfare Department, every child of every group (pre, in, or past, school) can be sent to his own doctor's office and examined in a few days, without causing any special flurry.

Since CALIFORNIA AND WESTERN MEDICINE has been agitating similar methods, we have been told that some doctors would not do the work. We don't believe it, but let us find out who they are, if any. There are plenty who will. Again we have been told that some doctors would neither examine nor treat the poor without pay. Again, we don't believe it. But again let's find out who they are, if any. And again, there are plenty who will assume the privilege.

Personal health service—preventive and curative—by your own doctor, or your own personal health counselor, as President Vincent of the Rockefeller Foundation prefers to call him, is a mighty fine health-promoting slogan.

A little more encouragement of movements in this direction and more public health departments will devote more of their time and money to valuable and much-needed *public* health work and less to the practice of personal health. Finally, and most important, it will make unpopular—to extinction—the fad of practicing medicine by incompetent organizations and groups and the pestering of the giving

public for funds with which to propagate themselves. Every five-hundredth person, including men, women and children, in California is an educated doctor of medicine whose office is the only kind of health center our people need. Why centralize groups of them—these same doctors—in “health centers” with expensive overhead that the public must support?

EPHEDRINE, A PROMISING THERAPEUTIC AGENT

Tasted by the Emperor Shen Nung about 5100 years ago and placed by him in the “medium class,” and described by Li Shih Cheng in 1596 A. D. as a diaphoretic, circulatory stimulant, antipyretic, cough sedative, etc., ephedrine emerged from seclusion in 1887, though really its possibilities have been fully revealed only within the last two years. Ephedrine is the active alkaloid of *Ma Huang*, or *Ephedra vulgaris* var. *helvetica*, closely resembling epinephrine in its actions qualitatively, but differing quantitatively and in some other important particulars. Recent studies of the drug, which is an ingredient of many famous Chinese prescriptions, have been made by the Chinese pharmacologist, K. K. Chen, and by Chen and Schmidt of the Peking Union Medical College. Fortunately, the results of a very recent clinical study made by Miller of the University of Pennsylvania Hospital, supported by the Council of Pharmacy and Chemistry of the American Medical Association, parallel and confirm those of the animal work by Chen and his associates. The promising therapeutic usefulness of ephedrine and its advantages over epinephrine merit attention at this time, though undoubtedly further and extended clinical trial, which is promised by Miller and others, will finally determine its place in the therapeutic armamentarium.

The crude drug, *Ephedra vulgaris*, yields two alkaloids, namely, ephedrine and pseudo-ephedrine, the latter being isomeric with ephedrine and their physiological actions are identical. Ephedrine was first isolated by Nagai in 1887. Its formula is $C_{10}H_{15}N$, and chemically it is stated to be phenyl 1-ol 1-methyl 2-methylamine 2-ethane. Its salts crystallize well and dissolve in water. According to Chen and Schmidt, the watery solutions remain active after exposure to air and light for forty-five days. The solutions remain colorless and can be boiled without loss of activity. There is no doubt, therefore, that ephedrine is more stable than epinephrine and this is a decided advantage. Its greater stability in vitro suggests at once that its pharmacological actions would be more lasting than those of epinephrine, and this was found to be the case in the careful and extensive studies of Chen and Chen and Schmidt.

The outstanding effect in animals, according to these investigators, is circulatory stimulation, characterized by marked cardiac acceleration and a sustained rise of blood pressure lasting 30 minutes and longer. The cardiac acceleration is due to stimulation of the stellate ganglia and the accelerator endings, for the drug stimulates the heart when it is applied locally to the stellate ganglion, and also when perfused through excised hearts. With moder-

ate doses, the heart volume is increased and the rate slowed as the maximal level of blood pressure is reached, thus resulting in an increased output of blood from the heart. With high doses and concentrations the heart is depressed and finally stops from direct paralysis by the drug, though the stoppage is usually preceded by fibrillation. As a result of the increased cardiac output, the diuresis later is increased, though in the beginning it is decreased owing to the marked constriction of renal vessels. The renal vessels share in the vasoconstriction of splanchnic vessels in general, and this peripheral constriction is largely responsible for the initial rise of blood pressure produced by the drug, but later the cardiac acceleration outlasts the vascular constriction and, hence, the sustained pressure is largely cardiac. The vessels of the extremities are much less constricted, the coronary vessels being dilated and the pulmonary, unaffected. Atropine and section of the vagi do not prevent the circulatory effects, and, hence, they are of sympathetic origin.

Other effects are inhibition of the intestine, stimulation of the uterus, relaxation of constricted bronchi, mydriasis lasting about one hour, and increase of salivary, sweat, lymph and gastric secretions. Pancreatic, biliary, and intestinal secretions are unaffected. In man, slight sweating without nausea occurs after taking 0.06 gm. by mouth. The drug cannot be detected in the urine after daily intravenous doses in rabbits, and is presumably destroyed slowly. In a study of twenty-two dogs suffering from different kinds of shock and hemorrhage with low blood pressures, Chen found that 2 to 3 mgms. per kilo of ephedrine intravenously promptly raised the blood pressures. The beneficial effects in anaphylactic shock lasted not longer than one hour and in all other shock conditions for about, or not over, three hours. The drug was ineffective when the pulse was imperceptible, the blood pressure was low for long periods, respiration ceased, and when hemorrhage exceeded 25 per cent. Chen thinks ephedrine breaks the vicious circle of shock, bringing more nutrition to the heart itself, the medulla and other organs, the pulse rate being invariably increased in the shock conditions. He feels it could be used beneficially in surgical shock and hemorrhage.

According to Chen, the toxicity of ephedrine is rather low. The minimum fatal dose intravenously for rabbits, cats and dogs is about 0.07 gm. per kilo. In rabbits, the fatal dose by mouth is 0.6 gm., intramuscularly, 0.34 gm., hypodermically, 0.36 gm. and intraperitoneally, 0.39 gm. per kilo. Convulsions occur only on intravenous injection, and death is due to cardiac stoppage. Recovery from sublethal doses is complete. The ordinary effects of ephedrine can be demonstrated in animals with doses of from 0.25 to 0.5 mgm. per kilo intravenously; and also from 10 mgms. hypodermically or 25 mgms. per kilo into the intestine. In man, 40 to 100 mgms. by mouth cause a definite rise of blood pressure and decrease in pulse rate, the effects beginning in thirty minutes and persisting more than two hours. This result in man has been fully confirmed by Miller. As for the animal studies, the work of Chen and Chen and Schmidt proves conclusively that ephedrine, just like epinephrine, is a sympathomimetic drug, and that it has distinct advantages over epi-

nephrene, namely, that its actions are more prolonged, those of epinephrine being fleeting, and that it is effective by mouth, while epinephrine is not.

The equally good results of Miller in the clinic deserve mention. Miller administered from 0.05 to 0.125 gm. ephedrine sulphate orally or hypodermically to eighty-four patients under controlled conditions. There were no unfavorable phenomena, the patients did not object to taking the drug, and some felt better. The most consistent change was in the systolic blood pressure, elevations occurring in seventy out of eighty-four instances, and amounting to from 10 to 40 or more millimeters of mercury. In thirteen cases no rise of blood pressure occurred, and in six there was an actual fall. The rise reached the highest level within from one to two hours, and then the pressure fell slowly during three or more hours to the original level. The blood pressure rises after oral administrations were about as marked as after the hypodermic, but the action was more prompt after the hypodermic injection. In most cases the pulse rate was slowed, due probably to reflex stimulation of the vagus center from the high blood pressure, and a compensatory phenomenon. X-ray showed the excursions of the ventricles and aortic shadows to be greater than before. The pulse was more forceful and the heart sounds were louder. All of these changes are strictly consistent with those found by Chen and Schmidt in animals. Presumably, the cardiac output is also increased in man and the diuresis, though variable, tended to be increased, according to Miller. Albuminuria occurred in patients with increased blood pressure, and whether there was an irritation of the kidney by the drug or not is not settled. The basal metabolism was increased in two out of four cases, but hyperglycemia was absent.

Important effects were observed on the nasal mucosa. The application of a 5 per cent solution of ephedrine sulphate contracted the turbinates in two and one-third minutes in all seventeen cases tested. The mucosa appeared thin and seemed to fit closer to the bone; the color was pale, but not as anemic as after epinephrine. Relaxation began at the end of two hours and thirty-five minutes. No irritation was present, such as occurs with epinephrine.

In certain disease conditions, Miller obtained definite benefits from ephedrine. Oral administration gave temporary improvement in two cases of Addison's disease, the paroxysmal attacks of a number of cases of asthma were relieved more efficiently than with epinephrine, the subjective sensations of urticaria were relieved, and there was marked temporary improvement in circulatory collapse. Miller concludes that the widest range of therapeutic usefulness of ephedrine will be in the treatment of asthma, hypotension and acute circulatory depression, and in certain congestive nasal conditions. A distinct advantage over epinephrine is suggested in the local treatment of nasal conditions, in nasal sprays for hay-fever, sinusitis, and perhaps as an aid in operations on the nose, etc. Other advantages over epinephrine have been pointed out above.

Thus, it appears that the newer methods of experimentation confirm, extend and rationalize the effects and uses of an ancient drug understood in

a general way and used quite intelligently, though empirically, by the Chinese thousands of years ago. We should be thankful for this belated knowledge, as indeed many a patient may be ultimately grateful to the possibilities that ephedrine holds out. It may be hoped that not only Chinese materia medica, but also that of other oriental and other countries, and even of California, whose medicinal plants have not yet been investigated, will furnish remedies as promising as ephedrine.

"THE WAY OF THE TRANSGRESSOR IS HARD"

The tragedy of the Murphy Memorial Hospital, now a familiar story to readers of hospital and health literature around the world, is at last revealing itself in all of its sordidness to the people of the beautiful little city of Whittier, California. Once the Murphy Memorial was a beautiful, well appointed, properly conducted hospital, pointed to with pride by physicians, hospital organizations and intelligent people everywhere. It was rated high in hospital directories as a scientific, health-serving institution and was rendering splendid service to a community much in need of such facilities.

Then certain cults and their cronies of the licensed medical profession got together, put on a referendum and not only *repudiated* a written agreement between the community and Colonel Simon J. Murphy, the benefactor who built and donated the hospital to the people, but what was even worse, *if possible*, they succeeded in "*opening*" the hospital as a place for all and sundry to practice their "systems" on those who might be credulous enough to trust their health in such circumstances. After all available means had been employed, without success, to save the situation, the Council on Medical Education and Hospitals of the American Medical Association and the American College of Surgeons removed the hospital from the accredited lists and it was dropped from all hospital directories of standing. The American Hospital Association dropped it from membership. The cultists and their followers were jubilant and broadcast their happiness and, unfortunately for them, their prophecies also.

WHAT HAPPENED

Politics, cultism and sciosophy generally have had full swing now for some five months. During that time the city council and their hospital board have quite thoroughly demonstrated every argument and

every prognosis made by the accrediting hospital agencies against the efficiency of such an institution. *The mayor has resigned under pressure, and the superintendent who played freely into the hands of the opposition has also resigned.*

But let Doctor Horace P. Wilson, an outstanding physician of the community, tell us, as he does in the Whittier News:

"The fiscal report of the board of trustees of the Murphy Memorial Hospital for the year ending June 30 has not yet been made public. *According to the law it was due July 31, consequently it is sixty days overdue.* This is quite contrary to the great publicity the board was to give to the affairs of the hospital. The city has been repeatedly informed that the hospital was full and self-sustaining. The last year of the old board, the hospital seldom had less than twenty-five patients for a daily average, there being over one hundred admissions in August a year ago alone. *For the last three months there have been for days but six to twelve patients in the hospital.*

"A report furnished Colonel Murphy at his request for the five months of the administration of the present regime was summarized by Mr. Darling, an expert, who says that the 'average monthly deficit for period of operation by the old board (no provision for reserves) was \$265.55; monthly deficit greater under present board by \$948.

"The unused taxes left by the old board amounted to \$32,600.79, whereas the present balance as per the report sent to Colonel Murphy is but \$28,038.11, with amount spent for equipment, leaving amount spent from tax fund for operation \$3,877.24.

"In addition to the \$3,877.24 from tax fund, the difference in cash on hand March 1 and July 31, accounts receivable and payable at the two dates, inventories, etc., enter into the figures in such a way as to cause the deficit for the five months the hospital has been under the new regime to total \$6,067.79, or an average per month of \$1,213.55.

"The contention of the new board that no taxes for the support of the hospital need be levied is not based on any evidence that the hospital is self-supporting, but it is evident that they are relying on using for operation the fund left by the old board for the purchase of equipment for the new wing."

"During this period," continues Doctor Wilson, "of five months the hospital has been open to all systems of healing, there has been just one case furnished by other than the medical profession, and that was a medical case.

"The superintendent has been paid monthly \$400 and maintenance. This is the equal of almost any superintendent's salary in the large hospitals. She has been absent from the hospital a great deal and has done personally no active work in the x-ray, maternity or surgical department. The former superintendent's salary was \$225. She was always on duty and could fill a little better than anyone else any position in any surgical or obstetric emergency. The books of the hospital are in such a deplorable shape that an accounting has been almost impossible. The very large deficit has been stated above.

"On August 7, 1925, the hospital, by action of the

American College of Surgeons, was removed from the approved list of standardized hospitals because of having forsaken every essential of such an institution.

"On September 10, 1925, it was removed from the list of accredited institutions by the Council on Medical Education and Hospitals of the American Medical Association. . . .

"We have been without an x-ray specialist, a dietitian, or a staff functioning with a co-operative hospital board, as the entire program has been at variance with the profession that do the work of the institution. The rules and regulations adopted by Mr. Smullin are the expression of a non-hospital mind and so contradictory that they are impossible of execution, and no attempt is made to live up to them.

"*Outside surgeons have almost abandoned the institution and those who have demanded that it be made an outlaw in the hospital world have contributed one patient in five months.* We have lost an endowment for all of this of \$200,000 that would have permanently solved the hospital problem and placed it beyond deficit or taxation perpetually. . . .

"Henceforth the hospital can only be maintained by heavy taxation or hospital drives to meet yearly deficits. It might be well for *those who have destroyed the morale and heart and soul of the institution* and have desecrated it in more ways than one to find some philanthropist who will restore to the institution and the taxpayer the \$200,000 the present regime has lost for it. It can't be done. No one will endow a standardless hospital.

"I regret the entrance into our civic life of political expediency and barter of fundamental civic values. We do not need this nor do we need slanderous, libelous sheets. They are the pernicious misdirectors of civic activities and it is deplorable that so large a number of our people fall for their insincerity.

"I regret beyond all telling the bitterness that has characterized the hospital agitation. It has emanated almost exclusively from those who are opposed to the reasonable standard to insure efficiency to the sick. From the onset I have insisted that the hospital was bigger than myself or any individual or the entire local profession and my own elimination from any official connection with it, by politics, was non-consequential. The institution will stand, serving the sick in some capacity, when all of us shall be as the ashes of the Tunician dancing girl in her long-forgotten sarcophagus."

If you can drive through ten miles of mud to ease the little child of a dead beat;

If you can do a podalic version on the kitchen table of a farm-house, with husband holding legs and grandma giving chloroform;

If you can diagnose tonsillitis from diphtheria, with a laboratory forty-eight hours away;

If you can pull the three-pronged fish-hook molar of the 250-pound hired man;

If you can maintain your equilibrium when the lordly specialist sneeringly refers to the general practitioner;

If you can change tires at 4 below at 4 a. m.;

If you can hold the chap with lumbago from taking back rubs for kidney trouble from the chiroprac;

Then, my boy, you are a Country Doctor. — H. W. Davis (Journal Kansas Medical Society).

Notes, reflections, extracts from correspondence, comment upon medical and health news in both the scientific and public press, briefs of sorts from here, there and everywhere.

ALBION WALTER HEWLETT

A PERSONAL TRIBUTE

BY WILLIAM EVERETT MUSGRAVE

THE WORLD HAS LOST A GREAT PHYSICIAN AND I HAVE LOST A FRIEND AND A BELOVED DOCTOR IN THE PASSING OF WALTER HEWLETT.

HEWLETT WAS ONE OF THE TEN BROTHER PHYSICIANS WHO SO FAITHFULLY, AND EFFICIENTLY ATTENDED ME DURING MY GRAVE ILLNESS OF TWO YEARS AGO. I LOVE THEM ALL, AND NOW THAT ONE OF THEM IS GONE MY SORROW IS PARTICULARLY POIGNANT AND MY UNDERSTANDING SYMPATHY ENFOLDS THOSE WHOSE LOSS IS GREATER THAN MINE.

THERE IS SOMETHING OF THE TRUE PHYSICIAN THAT ONLY THE SICK, REACHING OUT WITH FEEBLE CRAVINGS FOR HELP, EVER DISCOVER. GOOD DOCTORS SENSE THIS QUALITY IN THEIR WORTHY COLLEAGUES, BUT THEY CANNOT DESCRIBE IT. IT EXPRESSES ITSELF IN A PRACTICAL FRATERNITY OF SPIRIT AND EVEN IN SOCIAL CONTACT TO A DEGREE NOT FOUND AMONG ANY OTHER CLASS OF PEOPLE WHATSOEVER. THIS SOMETHING, NEBULOUS IN HEALTH, BECOMES AS CLEAR AS CRYSTAL THROUGH THE MORE FAR-SEEING VISION OF THE DOCTOR-PATIENT. IT IS BROTHERLY LOVE—*THE* BROTHERLY LOVE.

DESPERATE ILLNESS MAKES THE PHYSICIAN WISER. WHEN HE COMES BACK FROM LONG WALKS IN THE VALLEY OF THE SHADOWS, HIS LOVE OF GOD, HIS FAMILY, HIS PHYSICIANS AND HIS FELLOWMEN BECOMES MORE INTIMATELY A SUBSTANTIAL PART OF LIFE, AND IT COMPENSATES AMAZINGLY FOR SUFFERING.

THE DOCTOR-PATIENT, NOURISHED BY THIS EXPERIENCE, SEES BEYOND THE SURFACE INDICATIONS OF "PROFESSIONAL COURTESY" DEEP INTO THE HEART AND SOUL OF HIS ATTENDING PHYSICIANS, AND THE PICTURE IS PLEASING. IT REFLECTS WITH BRILLIANT CLEARNESS INTELLIGENT HUMILITY, THE SPIRIT OF SACRIFICE AND A SOMETHING ELSE TOO DIFFICULT FOR WORDS AND TOO SWEETLY SACRED TO DISCUSS, WERE WORDS AVAILABLE.

THIS EXPRESSES SOMETHING OF MY FEELING FOR EVERY ONE OF THE TEN OR MORE DOCTOR FRIENDS WHO CARED FOR ME DURING MY ILLNESS; AND NOW THAT ONE OF THEM HAS GONE I MOURN HIM AS A BROTHER AND WITH AN UNDERSTANDING THAT ONLY HIS OTHER PATIENTS CAN APPRECIATE.

OTHERS WILL TELL OF HEWLETT'S INFLUENCE UPON MEDICINE, HIS LEADERSHIP AS A TEACHER OF THE SCIENCE AND ART OF OUR PROFESSION, OF HIS VALUE AS A CITIZEN, BUT I SPEAK ON BEHALF OF HIS PATIENTS WHO LOVED HIM AND WHO MOURN HIS PASSING AS THE WISE, SYMPATHETIC, WHOLE-SOME, LOVABLE, CONFIDENT FRIEND AND HEALTH ADVISOR FOR BODY, MIND AND SPIRIT THAT EVER CHARACTERIZES THE TRUE PHYSICIAN.

HE HAS GONE TO HIS REWARD. MAY GOD KEEP HIS SOUL IN PEACE AND COMFORT HIS FAMILY AND HIS FRIENDS.

"Ich Dien" (I serve), which is the motto of the coat-of-arms of the Prince of Wales, might well be placed on a scroll surmounting the Caduceus, or Staff of Aesculapius, which is the insignia of the medical profession. The essential nature of the work of the healing profession, including not only the physician, but also the nurse, dentist, the pharmacist, etc., is *service*.—Ohio Health News.

The C. M. A. meets in Oakland April 26 to May 1, 1926, following the A. M. A. meeting in Dallas, Texas (April 19 to 23), with just the right connection to avoid wasting time. Many prominent officers of the A. M. A. and national figures from various centers who will take active part in the A. M. A. meeting have already agreed to return via California, and take an active interest in the program of our own sessions. These splendid colleagues should be properly escorted and chaperoned all the way from Dallas until they leave our territory through Nevada and Utah.

"A Malpractice Suit, with its attendant newspaper publicity, can work serious damage to your reputation, no matter how many years you may have efficiently and altruistically worked in public health endeavor."

This is only one short paragraph from a most suggestive and illuminating letter recently sent to all California Medical Association members. That letter, doctor, contains sobering facts that you ought to read, and suggestions that you should heed. Read it again.

Wise Health Boards in certain centers are maintaining distributing stations for antitoxins and vaccines in County Medical Society headquarters.

There's the germ of a big idea in such service, but it will not be seen by those health boards which are out to corral the practice of personal health.

"Anyone who is asked to check over the extensive printing and typewritten notes of a well-known institute (L. F. Donahue, Journal Med. Soc. N. J.) is aware that, aside from the legal, impressive-looking document, *there is very little that has not been already known by the family doctor*. It is true that his sympathy for the patient, and his knowledge of his previous psychology, has often prevented the family physician from *telling him* that he has a murmur which may be harmless, an old healed tubercle, or a similar inactive condition. This, the strange examiner greedily puts down. The patient naturally believes that his old family doctor was an old fogey, that only by the expert's examination was he saved from the dire consequences of a neglected lesion."

The Editor's Mail

—SEVERAL CORRESPONDENTS ARE INTERESTED and some of them so disturbed over the current controversy as to whether the proposed new University of California school or courses in nursing shall be controlled by the Department of Education or the Department of Hygiene, that they ask us to discuss the subject.

Inasmuch as part of medicine (optometry) is now being taught in the Department of *Physics*, we might suggest that nursing also be placed there. By all means let's teach our medical subjects together, and the Department of Physics certainly can teach nursing quite as well as it can diseases of the eye.

Physicians wonder what are the future plans for the medical school, hospitals, and Hooper Foundation in San Francisco. It looks to those outside as if what of medicine certain influences cannot transfer to the Berkeley campus they intend to destroy—all of which reminds one of this limerick:

*"There was a young lady whose dream
Was to feed a black cat on whipped cream;
But the first cat she found
Spilled the cream on the ground,
So she fed a whipped cat on black cream."*

—A Los Angeles member offers the following criticisms of CALIFORNIA AND WESTERN MEDICINE:

"First. I believe that it is absolutely essential that every article that is supposedly original or is listed as original should have a bibliography, so that one can look

up the authority quoted. When this is not done it causes men to write poorly—they do not look up the literature on the subject; and this, as a rule, results in a rehash of articles that have been published many times before.

"Second. Original articles received by the editor should be re-read and criticized by men interested in the particular branch of medicine, to determine whether or not they are real contributions to the literature, having in mind one article that was published in the last Journal by one of our local colleagues, in which I find that many questionable references are made, as well as opinions that have been disproven in recent literature."

Comment—The first of these criticisms has been anticipated and answered many times in CALIFORNIA AND WESTERN MEDICINE, and our present custom was approved officially by the Council of the California Medical Association. In any event, the doctor does not criticize the editor nearly as much as he does the authors, and he takes a responsibility we would not take, and do not believe to be true, when he says that the lack of publication of bibliographies "causes men to write poorly . . . and produce a rehash of articles that have been published many times before."

The suggestion made in the second criticism has been a constant practice of CALIFORNIA AND WESTERN MEDICINE for so long that we thought everybody knew about it. The article apparently complained about was read and endorsed by more than one specialist in the field covered by the article, acting as confidential editorial councilors. One of these editorial councilors was a close and particular friend of the man who makes this criticism.—EDITOR.

—W. W. Cross, M. D., Oakland—You probably have learned that I have moved from Fresno, which will make it necessary for me to change the card which I have in the Journal. As I intend to devote my entire time to genito-urinary work, I should like for the card to state that. The form as enclosed is what I desire to appear in the Journal.

—Luther M. Boyers, Berkeley, sends us letters and some amazing literature from the William Bannerman Company of Chicago. They claim that one or a few injections of their solution will cure varicose veins, and that it is an effective remedy for a long list of other ills.

The letters and "literature" have been forwarded to the Bureau of Investigation of the American Medical Association.

A. Gottlieb, Los Angeles, closes a letter upon other matters by saying: "I wish again to congratulate you upon the wonderful and continually growing success of CALIFORNIA AND WESTERN MEDICINE."

—I am enclosing a paper with illustrations and x-ray plates for your use in CALIFORNIA AND WESTERN MEDICINE. If you do not feel that this is a suitable subject for our magazine, I should appreciate the return of the copy and photographs.

I shall appreciate your editorial comments on the construction of the paper, as you have helped me in the past and I know the value of your opinion.—A. J. S., Los Angeles.

—I am returning the corrected manuscript. Your corrections certainly materially improve the paper. I thank you.—P. O. S., Los Angeles.

PUBLIC OPINION or something else has influenced the Ford Hospital in Detroit to materially change its financial methods.

If reports regarding the change are true, the Fords have jumped from the frying-pan into the fire, and when properly scorched in the new position they may be expected to jump again.

Rub—Did you see much poverty in Europe?

Dub—Yes, and I brought some of it back with me.—Life.

THERE ARE NINETEEN STATES and territories that do not accept the National Board of Medical Examiners.

California is one of them, *and it is in poor company*.

Hobbs—I really believe you have stopped your worrying. What brought about the change?

Dobbs (cheerfully)—My troubles are more real than they used to be.—Boston Transcript.

California, Nevada, and Utah Doctors Publish Elsewhere:

[Note—Members of the California, Nevada, and Utah Medical Associations are invited to supply the editor with reprints or marked copies of magazines containing their articles or very brief abstracts. All that we receive will be noted regularly in this space.—Editor.]

—Wallace Irving Terry, San Francisco (Journal Iowa Medical Society), writes on "Goiter."

—John V. Barrow, Los Angeles (Journal Iowa Medical Society), writes an article on "Intestinal Protozoa and Chronic Diseases, With Especial Reference to Chronic Arthritis."

—F. M. Pottenger, Monrovia (Better Health, November), tells of "The Role of the Preventorium in the Tuberculosis Program." "If tuberculosis," says Pottenger, "as we find it among children, were given the attention that it deserves in this generation, the amount of clinical tuberculosis among the adult population of the next generation would be greatly reduced."

—L. M. Boyers, C. A. Kofoed and Olive Swezy, Berkeley, California, write on "Chronic Human Amebiasis: Diagnosis and Treatment on Basis of Encystment in the Liver Area," in the Journal of the American Medical Association, November 7, 1925.

—Adolph A. Kutzmann, Los Angeles (Better Health, November), tells a timely story about "Backache and Kidney Pills."

—John W. Shuman, Los Angeles, and William C. Allison, Los Angeles—"Hypernephroma of Bone—Case Report" (Medical World, August, 1925).

—William Manwaring, Stanford University (Better Health, November), continues his series of entertaining and informative dialogues—"A Physician's Conversations With His Son."

—Miley B. Wesson, San Francisco (Northwest Medicine, February, 1925) —"Diseases of the Prostate and Their Treatment." The author believes that:

"All males who have never reveled in 'petting parties,' been guilty of excessive masturbation, or suffered from gonorrhea will probably avoid the discomforts and dangers of chronic prostatitis. This ailment can be cured, but the treatment takes years. . . . In fact, all diseases of the prostate are curable if they are diagnosed promptly, but there is no excuse for medicinally treating a surgical prostate until the patient is beyond the curative stage."

—In another article (Journal of Urology, June, 1925), Wesson writes on "Cysts of the Prostate and Urethra," a monographic report with bibliography.

—Randolph G. Flood, San Francisco (American Journal Dis. Children), writes of the "Acid Effect of Hydrochloric Acid and Lactic Acid Milk." He concludes that:

"1. Hydrochloric acid milk exerts a marked diuretic action not shared by lactic acid formulas.

"2. The total acidity of the urine, which is the measure of the acid effect produced by any ingested acid, is markedly increased by hydrochloric acid, but is little changed by lactic acid milk.

"3. The reason that lactic acid has little effect on the total acidity of the urine is probably because it is completely oxidized in the blood stream, and, therefore, has little effect on the acid base balance of the blood plasma."

—LeRoy Brooks, San Francisco (Better Health, November), discourses in popular language on "The Other Fellow's Blood—Its Uses."

—P. J. Hanzlik and M. L. Tainter, San Francisco (Archives of Internal Medicine, October 15, 1925) write on "Blood and Symptomatic Changes Following the Intra-

venous Administration of a Variety of Agents and Solutions."

—Zach B. Coblentz, Santa Maria (Journal A. M. A., October 10, 1925), discusses "Cysticercus of Skin."

—William J. Kerr, G. D. Delprat, N. N. Epstein, and Max Dunievitz (Journal A. M. A.) discuss the rose bengal test for liver function. Former papers by the authors are followed up, and they believe that "further observations confirm our earlier opinions of the value of rose bengal as a test for liver permeability and gross function."

—W. E. Musgrave, California (Better Health, November), under the title of "I Am a Doctor," replies to the vicious attack upon physicians by William Johnston published in Collier's of September 5.

SOME OF OUR NEWSPAPERS are again selling display space to that nostrum—"Lydia E. Pinkham's Vegetable Compound." Samuel Hopkins Adams exposed this "female weakness remedy" nearly twenty years ago. He showed that the Pinkham woman died in 1883, but that alluring advertisements still invited credulous, stupid women to write to Mrs. Pinkham. As far back as 1918 the government pronounced this cure-all *misbranded*, in that its promoters "falsely and fraudulently" claimed it to be an "effective remedy" for "falling of the womb, leucorrhea, etc.," when in "truth and in fact" says the notice of judgment, "it was not." The remedy also contained 19+ per cent of alcohol.

The revived up-to-date advertisements are more subtle in their language, but how newspapers can harmonize their *own ethics* with the facts in the case is best not explained.

ANCIENT PHILOSOPHY that is still modern finds itself provocatively illustrated by:

Inquiring Visitor—To what do you attribute your long life, uncle?

Oldest Inhabitant—Well, I don't rightly know. Several of them patent medicine companies is bargaining with me now.—Princeton Tiger.

With Other Medical Editors:

—JUST WHAT DOES BIRTH CONTROL MEAN? Does it include the use of preventive measures to conception? Does it include continence? Does it include abortion? Does it include Spartan infanticide? Does it include pre-adolescent or post-adolescent sterilization? Then, too, whose birth is to be controlled? Only the defectives, the criminals and the diseased, or may it not become fashionable for Jones to have his wife sterilized before or after marriage, or Mrs. Smith her husband.

And who is to control the controllers? The governor, the legislature, the doctor, the lawyer, the butcher, the baker, the unmarried or the married, or a conglomerate board of these elements?—Virginia Medical Monthly.

—NEVER IN THE HISTORY OF THE WORLD has there been so much propaganda adroitly and skillfully spread among the people as is found today. The fate of nations, institutions, people, politics, religion, theories, and objects of commercial gain, each is linked up with propaganda spread by articles in the lay press, by lectures from the Chatauqua platform, sermons in our churches and speeches before various organizations, and last but not least, the talks over radio. Just at the present time the American people are being treated to a series of newspaper articles on health problems, presumably under the authorship of medical men, that are spreading propaganda which in no sense has the endorsement of reputable and ethical medical societies, or medical men as individuals.—Journal Indiana Medical Association.

—THIS LAND OF OURS has ever been tolerant and even overzealous in seeing that the vociferous and loud-spoken should have all the air and opportunity necessary to relieve their overburdened chests. . . .

One lurid pamphlet quotes with great gusto opinions of men so eminent that one had a title of M. A., D. C. L.,

M. R. C. S., and L. R. C. P. A man with so distinguished a title doesn't need meat—he doesn't need anything except the great outdoors where men are men.—New York State Journal of Medicine.

—The Medical Society of the State of New York has many kinds of service to offer to its members. It is organized on the mutual plan. Its members govern the society and share in its profits. The society is what the members make it, and its profits depend on the amount of investment which the members put into it, and how well they manage it.—New York State Journal of Medicine.

—There is a real danger in anti-scientific legislation, for Truth seems always hidden by the blind spot in man's eye. An example has been set for the passage of anti-vivisection laws; irregular practitioners are gaining their point in many states, and it is becoming increasingly difficult to retain compulsory vaccination, even where it is still practiced. *For every one to kindle a light there are ten to extinguish it. It disturbs their sleep.*—Boston Medical and Surgical Journal.

—Chapin, in calling attention to Goethe's remark that blood was a very peculiar juice, added that the same could be said of milk.

It constitutes the food of the young of all mammalia, but when it is produced for commercial purposes it has long been recognized as being the most useful food and also the most dangerous. At times milk has been known to have been the cause of epidemics of many types of disease, and during certain of these the question actually arose as to whether its dangers did not outweigh its value as a food.—International Medical Digest.

—MARYLAND'S so-called "Six Months' Law" attracted wide attention when it was passed in 1916. The law forbids separation of mother and babe for the first six months of the infant's life. Before the passage of the law, one illegitimate child in four died during the first six months. The rate has now been reduced to one in twelve, which is one and one-half times higher than the death rate in legitimate children.—Colorado Medicine.

—THERE ARE EVEN HEALTH AGENCIES that frequently inaugurate campaigns to "educate the doctors" to the need and value of periodic health examinations.

Acutely aware of these "beneficent and magnanimous efforts" in their behalf, the physicians travel on—keeping abreast of the developments in scientific medicine, taking part in their County Society and State Association activities, giving their patients the very best of the skill and knowledge, and doing everything within their power to make the community in which they live, a better, safer, healthier, and happier place for their neighbors.—Ohio Medical Journal.

—The white man is not adapted for permanent residence in a tropical climate; neither, it seems, is he by reason of his general physical and mental "make-up" intended for many of the artificial conditions under which he now lives, including the heated atmosphere of most interiors in the wintertime. Too much luxury, perhaps (overheated air may be regarded as a luxury), tends to deteriorate physically and mentally.—Medical Journal and Record.

—Another new A. M. A. publication, "Archives of Pathology and Laboratory Medicine" (Journal A. M. A.), will shortly make its appearance monthly. The editorial board includes William Ophuls as the Western representative. This new venture will cover a most important field of medicine, and we bespeak its support by our members. We are delighted that the trustees have honored a California physician on their editorial board.

—ONE NEED NOT MARVEL at the credulity the people manifest in regard to all kinds of fake remedies and mystery methods of healing. Most of us were raised that way.—Journal Kansas Medical Society.

—Getting Out the Journal

Getting out a bulletin is no picnic.

If we print jokes, people say that we are silly.

If we don't print them, they say we are too serious.

If we print original matter, they say we lack variety.

If we publish things from other papers, we are too lazy to write.

If we stay on the job, we ought to be out hustling news.

If we are hustling news, we are not attending to business in our own department.

If we don't print all contributions, we don't show the proper appreciation.

If we do print all contributions, the paper is filled with junk.

Like as not someone will say we swiped this from an exchange. So we did.

We got it from the Illinois Medical Journal.

Many of our Disabled Veterans are making a living as are other citizens. Those of them, and they are numerous, who are doctors, buy from their "buddies" engaged in business. They also are trying to make a living selling the same sort of service they rendered during the war. The veteran who sells automobiles or groceries would feel discriminated against if the government became his competitor, precisely as they are urging the government to compete with those veterans who practice medicine for a living.

We all want to see every veteran have all the skillful medical care he needs for himself and those dependent upon him. We all, also, want him to have this service free when need be. BUT there are thousands of the best doctors we have—themselves veterans—who are willing and glad to serve their ambulatory sick fellow-veterans as individuals for nothing, or what the patients feel they can afford to pay. When the government goes into the "diagnostic clinic" business, it is discriminating in a useless manner between those who served.

"The Michigan State Medical Association has taken the following stand:

1. The group or associated body of physicians is amenable to the same regulations and principles as is the individual physician.

2. The fact that two or more physicians have formed a partnership, group, or clinic, does not grant them special publicity privilege.

3. The creation of a group or clinic does not convey unusual publicity privileges, even though part of their activities may be of a charitable type."

ONE OF OUR ESSAYISTS has complained to this editor that his use of the noun "pathology" to indicate a pathologic condition was allowed to get by the editorial blue pencil. Our defense is, that the abuse of this word in statements, such as "there was no pathology in the appendix," has become such an extensive habit—reprehensible habit—that our editorial staff must be excused for overlooking a mistake that they have to correct so often.

— Never Again

"Ruth, dear, won't you offer little Archie part of your apple?"

"No. Eve did that and she's been criticized for it ever since."

"James Compton, Secretary California State Board of Chiropractic Examiners, recently announced that in the last few months the board had licensed 1542 chiropractors."

What About California?—"According to E. S. Elwood, managing director National Board of Medical Examiners, candidates holding the certificate of the board will be granted a license to practice medicine without further examination in South Dakota. *This makes a total of about thirty-three states, besides Porto Rico and the Canal Zone, which accept the board's certificate.*"

According to the Public Press:

—Newspaper editors are getting quite a lot of fun out of Doctor Copeland's proposal to establish "restaurants at which patrons will be able to get just the sort of food they need for whatever may be the matter with them."

The New York Times, for instance, considers this an "alluring prospect," but the editor wants to know if the "waiters are to be diagnosticians, or shall each restaurant have its own staff of expert diagnosticians." "Perhaps," continues the Times, "the Senator himself will be on duty an hour or so a day. His newspaper articles long since demonstrated that he knows all there is to know about every mortal ill and just what should be done for each of them."

All of which is but another of the numerous reasons why health-promoting publicity for the public press should be impersonal and given out in the name of a recognized medical organization rather than that of an individual. The Better Health Service is the best example of how to do this.

—More than 25,000 mental disease patients of the 250 million dollars' worth of state hospitals of the United States are out on parole. A regular avalanche of protest against this is widespread.

And who would not be nervous among politicians who traffic thus with the public health?

—The expert statisticians have again lengthened the life span several years since this editor was last in the city. It seems that a fellow must go to town every day to get the "latest" about long life. If he stays in the country for weeks at a time his "thickness" is liable to shine most prominently in his lack of information about the last decade that has been added to life.

What we would like to know is, what is to be done with all the centenarians. The "homes," asylums, and hospitals are now full to overflowing, and goat glands are said to be running short. At least they are selling for higher prices.

—A nurse attending a scarlet fever patient broke quarantine and went to a barber shop to have her hair bobbed.

Only physicians and nurses can *fully* appreciate the potential dangers in such a—to be generous—stupid action.

—Arbuthnot Lane is at it again. He resembles some other tourists who make brief visits to foreign countries and leave a trail of press clippings behind them that would make a less egocentric guest blush for shame. Our organizations of doctors should exercise greater care than they sometimes do in selecting foreign physicians to be our guests.

—Cucumbers are coming into their own again. This latest fad to "purify the system" and weigh just one hundred pounds is off to a fast start. It is sponsored by fashion dictators and cooks, and when these combine their influence they get results—with fools.

Doctors will benefit, but what a ghastly business to have to lose sleep to cure fools with the bellyache.

—Another free-for-all personal health clinic for children has been opened in San Francisco. Proponents of municipal operation of public utilities about which we are hearing so much might get valuable lessons from our rapidly extending "municipal operation" and direction of personal health.

—"Looking-glass education" is the latest addition to the public school curriculum for "flapper grade" girls. This is humorous or pathetic, depending upon the point of view. But when such arrant nonsense is credited (?) to "health education," as it is, uglier characterizations are indicated.

—Two more of our good doctors are defendants in a \$100,000 malpractice suit. In this instance they are accused of putting a plaster cast on a woman's leg so tight that circulation was interfered with, making subsequent amputation of one leg necessary.

Moral: Well, you know what it is.

—Secretary Hoover, in a recent talk to the Associated Advertising Clubs of the World, told them that the milestone which marks the passage from a trade to a profession is the establishment of group ethics. He pointed out that in the law, medicine, engineering, it is not only training and skill which is required, it is the elevated code of relations with fellowmen, the incorporation of responsibility to the community into the daily task, the insistence upon a high sense of service given, that marks their distinction.—Ida M. Tarbell (McClure's).

—"The daily motion picture audiences of America include nearly a million children—a juvenile throng that would fill to overflowing two thousand average movie theaters.—McClure's.

—A professor at one of our universities insists that the brain does not tire.

"The brain-weary businessman is a fetish of the popular imagination," claims Professor Miles. "He may be bodily weary, but brain-weary never. If our bodies could stand it, our brains could function twenty-four hours a day, and be as bright in the twenty-fourth hour as they were in the first."

One of our readers in calling our attention to this statement adds the note that the "hoe doesn't get tired, but the gardener does."

—In 1922 the California Medical Association adopted a resolution whereby the office of every member became a health center, to render services for a fee commensurate with the ability of the applicants to pay. That the plan is sound, Dr. Schmitt says, is demonstrated by the fact that one-third of the persons applying to the Health Center of the University of California have been referred to private physicians.—University of California Clip Sheet.

—Doctor Copeland (Collier's) tells the world that "The doctor of the future will be a practitioner of preventive rather than corrective medicine." He develops this theme in the usual manner. We would like Doctor Copeland to tell us, when his dreams come true, who is going to care for the 3,500,000 people who are sick every day—and know it. Then there are from 60 to 75 per cent of the other 110,000,000 who are not well, but they are still able to make the grade.

It's all right, of course, to preach prevention, but some millions of us who have been through the mill, and realize that we must go again, are more concerned to have competent doctors to advise and assist us with that skillful, sympathetic service that most of them so effectively employ than we are with the practitioner who will tell us how to avoid something else.

—The effects of "emotional sprees," or "nervous jags," on the health are almost, if not equally, as bad as the results of an alcoholic spree.

A lot of people who get drunk regularly are sick, and practically all of the people who indulge in emotional sprees are sick—mentally sick, nervously disordered. They are victims of deficient self-control.—W. S. Sadler (American Magazine).

—SOME DOCTORS did so much unrestrained talking about poor old Doctor Blazer's unfortunate family matters that the newspapers quite noticeably twisted the crime of one man into another arraignment of a great profession.

We would much prefer to be in Doctor Blazer's fix to that of some healthier doctors, if they mean what the papers quote them as saying. When talking for publication, it is well to remember these lines from Omar Khayyam:

The moving finger writes: and having writ
Moves on: Nor all thy piety nor wit shall lure
It back to cancel half a line, nor all thy tears
Wash out a word of it.

—We do wish the American College of Surgeons would engage a wise publicity director. Every time these estimable surgeons hold a meeting the press-clipping agencies deliver a mess of mud-slinging that has besmeared all the other members of a great humanitarian profession. The recent Philadelphia meeting was no exception, and too much dirty linen was washed in public. Of course, all destructive criticism of doctors or undue claims

by doctors are "news." The more sensational they are, the greater the "news value."

We do not for a moment believe the American College of Surgeons endorses or connives at much of the publicity that accompanies their meetings, and some of it is unavoidable. But much of it would be avoided by a good publicity director, and the reputations of physicians, some 145,000 of whom are not members of the "college," would be cleaner than they are with the obviously ineffective methods now in vogue.

—"A noted biologist" and "leading authority," say displayed news dispatches, implanted the glands of young untrained rats in the bodies of old, educated rodents. The veterans, while rejuvenated physically, lost their memory, even forgetting the location of their home cages.

Goodness gracious, we thought that was what "old rats" got "rejuvenated" for. Doctors have assumed right along that if rejuvenation restored a failing sexual power, it would at the same time "rejuvenate" the desire to find mates often away from the home cage. A sort of amnesia, as it were!

—A professor gets display space in some newspapers by announcing the "discovery" (?) that light travels in waves of different lengths.

Too bad we abolished the old-fashioned school books, isn't it?

—An Arizona doctor claims that "graded doses of sunlight will cure all the ills of humanity."

This obtained prominence because the doctor also said that "California is the most ideal place in the world for the new sunlight treatment."

Some thousands of years ago the Athenians made a similar claim for their sunlight. Then came the sun worshippers—but why spoil the story?

—Two "noted French pathologists" have "discovered" a substance with which, by the simple process of a hypodermic injection, people's weight may be changed to meet the changing styles in clothing or otherwise.

That was cabled "news" on the same day of the announcement that Paris "dressmakers" had decreed 100 pounds as the "society weight" for this season.

Now that's "team work"!

A United Press story published by some of the less particular newspapers announces another revival—as something "new"—of the story that lead will cure cancer. As usual a "noted" physician—a foreign one—is credited with the "discovery."

It was a great day for cancer cure fakers when newspapers stopped selling them advertising space. They just became a little smarter and now get their stuff into the news columns—of some papers—for nothing.

Disgusting, yes. Criminal, often; but there is encouragement in noting from press clippings that fewer newspapers now publish such stuff.

—Representatives of competing press services in England must be very gullible or conscienceless to cable new "cancer cures" to our papers so frequently.

One day recently the front page of some newspapers contained reports of the discovery of another cancer cure by a "noted British doctor," and another story of the discovery also by a "noted doctor and manipulative specialist"—probably a chiropractor—of some sort of a gland that is responsible for women changing their minds so frequently and arbitrarily."

OVER ONE HUNDRED MILLION PEOPLE in the United States escaped death or injury last year by twenty-five million automobiles.

That's far more than escape similar consequences from tuberculosis, syphilis or gonorrhea germs. Effective "safety-first" methods are easier to apply to germ traffic than they are to motor traffic. A modicum of applied intelligence is all that is necessary in either case. In proportion as we succeed in either case, is our intelligence.

IF NEWSPAPER ARTICLES about some of them are significant, the plastic surgery surgeons or "beauty surgeons," as they are being dubbed by popular writers, are liable

to be the next group that will want medical ethics modified to meet their "peculiar conditions."

Plastic surgery, as a fine and legitimate medical specialty, is quite definitely drifting into treacherous waters through the amazingly stupid conduct of some doctors who know better and who should be ashamed of their conduct.

It is generally recognized by the more progressive health authorities that house fumigation, as heretofore practiced, is of almost no value in the prevention of the spread of disease.—Journal A. M. A.

"THE MOST COMPETENT AUTHORITIES believe that the only completely effective method of determining diseases and defects in the eyes of school children is through an examination by an ophthalmologist."

And yet most of the extensive report of the National Committee for the Prevention of Blindness, from which this was taken, is devoted to telling teachers how to do it.

"A 'HEALTH DEFECT' is a condition actually or potentially detrimental to a child's health or efficiency; the type that should be recognized and corrected if remediable."

If this is not profound enough to please, read this. Both are from a report of The National Committee for the Prevention of Blindness.

"'Borderline' is a term used to refer to the line which separates the normal condition from the health defect, anything of less degree than the border line being included with the normal, and a defect of worse degree than the border line being considered a health defect."

Then this caution to the various groups of laymen who are replacing doctors in the care of the health of school children:

"Examinations of the visions of school children should be made in conjunction with general physical examinations in order that when a defect of visual acuity is found it may be compared with the child's general physical condition to determine to what extent the two are related in the case in question. General health and physical vigor are important factors in determining the degree of visual acuity possessed by children of school age."

We are delighted to receive so many messages commending the idea of devoting space to "Bedside Medicine for Bedside Doctors" and the substitution of this title for what was initiated as "Medical and Surgical Conversaciones." It is heartening to an editor to so often see refuted the alleged statement that doctors do not write letters.

THE BEST SUNDAY SUPPLEMENT we have seen in any newspaper was the BETTER HEALTH supplement issued by the San Francisco Examiner on October 25.

This eight-page enclosure consisted of sound health information for non-medical people. It was all prepared, as is the matter in the daily and regular Sunday Better Health Services, by educated physicians. *Yet no doctor's name appeared in the supplement.*

This is as it should be. The BETTER HEALTH Newspaper Services promote a cause, and not individual doctors.

San Diego's Medical Lectures—Dr. Henry Sewall, Professor of Medicine at Denver, will give a course of six lectures in San Diego, beginning January 4. His subject will be "Physiology." The lectures cover modern research in the metabolism of respiration and of the endocrines.

The lecture course is given by the San Diego Medical Lectureship Fund, raised among members of the County Medical Society, chiefly through the efforts of Dr. David Higbee.

THE TWO PRIZES offered by the C. M. A. are worth working for. The financial reward is not so great, but there are other compensations for the winner of a contest promoted by a great medical organization that will be of value to the successful author all of his life.

More complete information about these prizes may be found elsewhere in this issue.

W. C. Hassler, Official Public Health Doctor of San Francisco, tells the press that 8921 babies were born in the city last year, and 450 of them died before they were a year old.

If the some 200,000 women of child-bearing age only produce some 9000 babies a year, it's about time to soft-pedal the birth control publicity until we get back again to a "quantity production" basis.

Of course, it's fine to tell mothers again for the nth time monthly how to save babies when they get them, but goodness, let's also increase production.

What we would like to know is, where, how, from whom, did those university "students" learn that "the family is unnecessary to the progress of civilization"?

The answer to that question would apply to many others that are being asked—and it might prove illuminating enough to decrease taxes.

The Supreme Court of Appeals of West Virginia rules that this was an action for damages from an alleged injury from negligent and unskilful treatment by one of the defendant's nurses while the plaintiff was a paying patient at the defendant's hospital. The defendant filed a special plea, setting forth its character as a charitable institution. An objection to the plea was sustained and the plea rejected. The case was then certified to this court on the joint application of both parties to the suit, who desired a ruling on the sufficiency of the plea. The exact question involved had never been determined by this court. Public policy demands that charitable institutions be fostered and preserved. To this end, the law should deal with them more leniently than with institutions conducted solely for private gain. No human endeavor of any magnitude is immune from mistakes. No matter how strict a rule might be enforced against institutions of this nature, mistakes in treatment would occasionally happen. Employees and servants selected with ordinary care, however, will execute the charity with but few mistakes. If no care be had in their selection, mistakes will necessarily multiply. The purpose of the founders of a charity is to help those who need assistance. They propose, not unskilful or incompetent aid, but humane and efficient treatment. The subject of an employee's negligence is harmed instead of helped by the charity. The will of the donors is thwarted instead of served when an object of their beneficence suffers from such neglect. When administered by incompetent servants, charity, instead of being a great boon to humanity, may become a menace. One who enters a hospital expects, and has a right to expect, more skilful treatment than is obtainable in the home. If such institutions be not held to reasonable care in the selection of their employees, confidence in their efficacy will be shaken. Many who need, will fear to accept hospital treatment, and those who do apply therefor will lack the faith therein that is so frequently half the battle in the contest with disease. In order that the high purpose of the donors of a charitable hospital may be best served, that those who need aid may not hesitate to accept the charity, and to prevent as far as may be human suffering from acts of negligence and incompetence, it would seem imperative to require of those in charge reasonable care in the selection and retention of the employees. The fact that one is a paying patient does not alter the rule. Such patient is the recipient of the donors' gratuity only in a lesser degree than one who makes no payment. The hospital building, with its equipment, management, and its great possibilities for the alleviation of suffering, was provided by charity. In using the organization made possible and supported by that charity, a paying patient, to that extent, benefits by the charity. Because of its failure to allege that the defendant used reasonable care in selecting the nurse of whose negligence the plaintiff complained, this court holds that the plea as presented did not in terms state a defense to the action, and the judgment of the lower court is, therefore, affirmed. As stated in the syllabus of the court, *it is incumbent on a charitable hospital to use reasonable care in the selection and retention of its physicians, nurses and attendants; and for failure to do so it is liable for injuries due to their incompetence received by its patients.*—Journal A. M. A.

Medical Economics and Public Health

"From no other state during the past six or seven years," says the Journal of the A. M. A. in discussing the activities of the California Board of Medical Examiners, "have so many reports been received regarding the prosecution of illegal practitioners and the revocation of the licenses of physicians found guilty of criminal or illegal practice. In few states have such careful records been kept of those engaged in the various branches of the healing art."

"Recently, members of the diploma mills were dismissed on motion of the prosecution, because the authorities of San Francisco failed to provide sufficient funds to prosecute the cases."

Have You Registered Your Certificate?—Reports are coming to us of instances where doctors are running afoul of the law because they have failed to register their certificates to practice medicine and surgery with the county clerk of the county or counties in which they are practicing. This registration of the certificate with the county clerk is just as much a part of the law regulating the practice of medicine as is any of its other features. This oversight may be an extremely expensive one to a physician at the most inauspicious moment.

"If you do not think," says the Journal Indiana Medical Association, "that state medicine is a threatening evil, read some of the papers published in certain medical journals with a leaning toward welfare organizations, and listen to some of the talk of salaried public health officers and all-time professors in our medical schools."

Monkeying With the Narcotic Law—Too many of our good doctors are finding to their cost that the new narcotic law of California now in effect has vicious teeth in it. It is no longer possible to violate this law and smooth the matter over, because the law itself recognizes nothing less than penitentiary sentences. No judges or other people have authority to waive this mandatory provision of the law.

There may be grounds for debate upon the wisdom of enforcement officers in using under-cover agents posing as addicts to get a doctor into trouble by playing upon his well-known sympathies. The doctor who allows his sympathies to lead him into an infraction of the law as it now stands is inviting very serious trouble for himself and those dependent upon him. The law provides a method by which an honest physician can relieve suffering in an addict, and any doctor who makes the mistake of not obeying that provision of the law is unbelievably stupid.

"Just how broadly the courts will construe the California Chiropractic Act is not clear. By implication, the chiropractors of California may all use any drug or medicine except such as are 'included in materia medica,' whatever that may mean. The interpretation of the phrases, 'as taught in chiropractic schools or colleges' and 'as taught and practiced by the recognized schools and colleges of chiropractic,' is difficult. Probably the chiropractic proponents of these laws had in mind the possibility of extending the field of their activities from time to time through the simple expedient of inducing their colleges to enlarge their curriculums."—Federation Bulletin.

The National Committee for the Prevention of Blindness, makes these significant statements: "*'Diagnosis' and 'treatment' are terms which may be considered synonymous with 'detection' and 'correction.'*"

"That the schools should make every effort to discover cases of defective vision among pupils, is agreed generally; whether the schools are to be required to correct such defects is not yet decided.

"The greater the skill and training of the examiner, the more accurate will be the opinion given. Neverthe-

less, since cases of apparently defective vision and suspected eye disease are usually treated by skilled practitioners and not the examiner, the use of teachers and other non-medical examiners is justifiable as the most practical means for examining now available."

A movement is well under way in New York to establish and endow a national home for "aged, decrepit and indigent physicians." An appeal for funds is being made by a group of professional fund raisers to doctors of the whole country, and medical editors are asked to lend their assistance with publicity. The movement is a splendid one and is being promoted by a group of well-known New York physicians. But we fail to see anything national about it, nor, in our opinion, should charity for this purpose be maintained upon a national basis. At widest it is—or should be—a state affair. The doctors of any state can, and no doubt would under capable leadership, contribute and otherwise support a service for those who have served well the people of their own state. We strongly suspect that Western or Southern doctors, for example, would have to be very old and very badly off indeed before they would be willing to spend their last days in a "home" in New York, however comfortable and attractive it might be made.

Just the same, the publicity about the New York home will do good and may lead to an adoption of the idea in other communities.

Reports from 294 cities of over 10,000 population showed that eye inspections are now conducted by the following persons:

- In 58 cities, by school physicians alone.
- In 75 cities, by nurses alone.
- In 59 cities, by physicians and nurses in co-operation.
- In 42 cities, by classroom teachers alone.
- In 60 cities, by combinations of the three.
- In about 20 per cent of the cities, physicians alone examine the eyes.
- In 37 per cent of the cities, teachers and nurses make the examinations.
- In the other cities, examinations are made by any of the three.—From the Report of the National Committee for the Prevention of Blindness.

The toll of human life taken by automobiles last year in the United States was at the rate of more than two persons for every hour of the day, or fifty-five persons for every day of the year.—National Safety Council.

Kolb & DuMez (Therapeutic Gazette) estimate that in 1924 there were perhaps 150,000 addicts of morphine, cocaine, or heroin in the United States, but they further express the belief that the correct figures should be about 110,000.

"The legislation which has been passed," believes the Therapeutic Gazette, "to limit the ability of addicts to obtain these drugs has, heretofore, been passed for the benefit of a relatively small number of degenerates and has caused an immense amount of suffering among many thousands of worthy people who, not being cursed with an impaired morale as a result of inheritance, are deserving of consideration when such laws go into effect."

In some cities, as in Cleveland, Philadelphia, Boston, and Denver, the entire health supervision of the school children is under the Board of Education. In others, as in New York, Chicago, and Detroit, the Board of Health has charge of the medical inspection, working in co-operation with the school staff.—National Committee for the Prevention of Blindness.

During the calendar year 1922, the last for which data are available, there were 78,070 persons cared for in almshouses and 348,928 in homes, day nurseries, and similar institutions. In addition to these, there were in hospitals and other institutions for the care of the insane and feeble-minded and epileptics a total of 348,174 persons. Records show that more than 400,000 persons go out from our state and federal penitentiaries annually; many of those of our dependent classes, as well as many

of those in penal institutions, are suffering from preventable diseases which, in some measure, are factors in their dependency or delinquency.—United States Public Health Service.

American Protective League, another high-sounding title for an apparently new organization of the Bernarr McFadden publications, exponents of sciosophy and enemies of scientific progress. The list of these publications include:

True Stories, Physical Culture, Fiction Lovers, True Romances, True Detectives, Radio Stories, Muscle Builder, Dream World, Dance Lovers, Modern Marriage, Your Car, Movie Weekly, and The New York Evening Graphic.

Warning—A person alleging to be a representative of a life insurance company is working doctors by the hoary method of getting them to cash a check larger than the amount needed to pay for examinations for life insurance policies. He left quite a string of worthless checks in Vallejo, and no doubt by this time is using another name and the name of another insurance company than the one he used there. We have been asked to broadcast this information, which we do, but the necessity for broadcasting a warning against such ancient methods of graft should long since have become unnecessary.

A Doctor of Santa Monica sends an inquiry to the Board of Medical Examiners with a copy of a newspaper advertisement in which an optometrist uses the title "Doctor." Doctor Pinkham of the Board of Medical Examiners replies as follows:

"In response to your inquiry as to whether W. A. Lady, 213 Santa Monica Boulevard, optometrist (whose newspaper advertisement you forwarded to us), has a right to use the prefix 'Dr.' will state that optometrists are under the Board of Optometry and *we have no jurisdiction*.

"In the San Francisco Examiner of July 25, 1925, appeared an article stating that Attorney-General U. S. Webb had advised the State Board of Optometry to the effect that California optometrists cannot legally style themselves as 'Doctors' or 'Drs.' in prefixes, and can only add the affixes of 'Opt. D.' or 'O. D.' when they are graduates of an accredited school of optometry; also that no California optometrist may hold out to his prospective patients that he possesses 'special knowledge' of optometry as defined in the Act, *which Act* defines optometry as a mechanical and not a medical science. We believe this opinion of the Attorney-General will answer your question."

"The smallpox prevalent in American and Canadian cities during the first six months of 1925 was nearly four times as deadly as the type of the disease which occurred in 1923! This year there were recorded 3.5 deaths for each 100 smallpox cases; in 1923, this figure was less than one death per 100 cases.

"The smallpox menace is real; the experience this year shows that the disease is present all over the United States in a death-dealing form. A considerable proportion of unvaccinated persons, and especially of children, in the population of any city is simply tinder for an epidemic which may cause hundreds of deaths, prolonged disability, the complete paralysis of industry and commerce and the impairment of the reputation of the city. How much longer will the American population tolerate a loathsome disease which is entirely avoidable and which has, year after year, increased its power to kill?

"What of the future? Only thoroughgoing vaccination will protect the American and Canadian populations from an epidemic of deadly smallpox which, under present indications of indifference to vaccination, bids fair to rival the most destructive smallpox epidemics in public history. The choice between complete security from smallpox and a record which may well prove to be an indictment of our intelligence rests wholly with the people of the United States and Canada."

These statements are not from medical sources, but from the statisticians and business men of a great insurance company.

Last year I was supplied with a copy of The Christian Science Monitor containing a marked editorial which started out by speaking of "Edward Jenner, who conceived the delusion of vaccination and forced it on a world which is growing daily more skeptical of the worth of his discovery. . . ." It is amazing that anyone should speak of vaccination in that way. The so-called "delusion of vaccination" has, without question, saved the lives of tens of millions of human beings since the days of Edward Jenner, human beings who would otherwise have died of smallpox. I cannot doubt, further, that it has saved many other millions of human beings from serious illness due to that malady.—President W. W. Campbell, U. C., Better Health, November.

The United States Public Service announces that recently a large number of inquiries have been received for information concerning the so-called "National Health Service," with offices in New York and Washington. It is pointed out that there seems to be considerable confusion in the minds of the lay public as to whether the "National Health Service" is a government agency (U. S. P. H. S.) or a volunteer agency. The United States Public Health Service points out that publications of the "National Health Service" are written with manifest attempt to create the impression that it is a government agency, which it is not; that its field representative represents himself to be a physician, but is not, and that its "physician-in-chief" at one time was convicted of using the mails with intent to defraud and was sentenced to a term of four years in the Atlanta penitentiary.—Ohio Health News.

The "Equalization League" apparently is becoming active in efforts to "equalize" the California Board of Health; by which they mean to make it a mixed board composed of all varieties of "doctors by law."

Why not? If the state licenses these miscellaneous "sciosophists" and *thereby approves them as competent to diagnose and treat the infirmities of individuals*, it is logical for the same authority (?) to authorize them to practice the far simpler profession of public health.

When physicians oppose this "equalization" move, as of course they will—even though it would add greatly to their business—watch the "sciosophists" yell mercenary! One of many interesting letters on "equalization" activities is published on page 541 of the November issue of *Better Health*.

According to the Public Press—

The "Soul and Body Clinics" have struck the snag CALIFORNIA AND WESTERN MEDICINE predicted they would strike when all the propaganda that a great church could influence was in full swing. Unless they are strikingly guileless the strong "soul group" knew precisely where they were going when they induced Doctor Cowles and other doctors to help them practice medicine. Cowles ought to have known better, but if press dispatches are approximately true he is more angry now than a good soul saver should be:

"There has come to the attention of the medical profession," Cowles recently declared, "hundreds of cases where men, women, and children have died horrible and lingering deaths because of the neglect resultant from priests playing on spiritual emotions."

In any event, we "labeled" those "soul and body clinics" correctly a long time ago.

The State of New York spent in 1924 \$580,762 for the care of 911 syphilitic insane admitted during the year. The United States Public Health Service calls attention to the important facts that this expenditure of over half a million dollars is the cost of institutional care alone, in one state only, and for but one of the hopeless disabilities resulting from neglected or inadequate treatment of syphilis, either in the early or late stages.

Speaking in a Methodist church in Manhattan, a doctor cried out against the imperfection of the age. He was Dr. Eugene Lyman Fisk, Medical Director of the Life Extension Institute. He said that, of 400,000 persons examined by the organization in twelve years, *not one*

perfect physique had been found. "More than 60 per cent of those examined," he said, "have been found in need of some important medical attention, and practically all have required some modification in their mode of living."—TIME.

In the serious matter of whether eye tests of school children shall be made by physicians, nurses or teachers, the requirements of the law are again important factors. In Alabama, California, Illinois, Indiana, Kansas, New Jersey, New York, and Pennsylvania, either physicians or nurses working individually or together, make the eye tests. In each of these states the law specifies that physical examinations either may be made or shall be made by physicians. In other states, such as Connecticut and Massachusetts, the *law specifies that the examination shall be made by teachers.*—Report of National Committee for the Prevention of Blindness.

Crab—A new advertiser, whose announcement begins in this issue, approached Mr. Flynn, our representative, recently with a request to advertise crab meat. We frankly admitted that we knew very little about crab meat, and neither did they. Under Mr. Flynn's direction, therefore, the prospective advertiser consulted Professor Hanzlik and other competent authority and brought for our information a prepared statement about this food which has proved so informative to this editor that we believe we are justified in utilizing space to pass extracts from it on to the medical profession as a whole. In brief, this investigation shows that:

"Japanese canned crab meat," which is now extensively imported, is prepared from what is known as the king crabs, which live in abundance in the northwest corner of the Pacific Ocean—off the island of Hokkaido, Seghalein Island and the Kurils, and along the coasts of Marine Province of Siberia and Kamchatka Peninsula, where the cold currents are prevalent. They never live in warm water.

The king crab has a very hard shell and unusually long and strong legs. It grows to quite a large size, sometimes weighing as much as twenty pounds. However, the ordinary-sized crabs for canning purposes weigh about an average of eight pounds—running, in length, from 3 to 4½ feet from the tip of the longest leg of one side to that of the other side through the center of the body. Crabs are caught with large nets, which are lowered down deep to the floor of the sea and left for a few days. Catching of females and small masculine crabs is prohibited by ordinance.

Unlike other crabs it is a clean feeder, and as it lives in clear cold waters remote from densely populated lands, its meat is quite free from the dangers inherent in scavenger shell fish and those that thrive in polluted waters. Its meat is sweet and finely flavored. The legs and body are covered with thin skin. When properly boiled, the skin turns to a fine strawberry color and the meat to a milky white. King canned crab meat contains 18 per cent protein, 3 per cent fat, and furnishes a fuel value of thirty calories per ounce, though the quantities are varied, according to seasons. According to some marine food authorities, it contains relatively large quantities of glycogen, which, in combination with its rich protein, gives so much more credit to its food value.

The canning of this food is becoming a great industry. In addition to canneries ashore, it is now packed extensively by what is called "floating canneries," steamers of 1000 to 3000 tons, provided with modern fishing and canning equipment.

The Japanese Government keeps a very close watch on the quality and methods of packing this crab meat. Under its auspices the Japanese Canned Crab Packers and Exporters Association was organized in 1923, comprising all of the packers, exporters and dealers, which exercises a strict control over every phase of the industry. Under the present inspection rule the goods are classified into four grades—fancy, choice, fair, and passed.

The food and commercial value of these crabs were long unknown. About twenty years ago, Mr. T. Domoto, the president of the North American Mercantile Co. of San Francisco, happened to hear that fishermen of Hokkaido were having a very hard time from crabs that so often tore their nets, and these crabs lived in such abun-

dance that it was impossible to provide against their damage. Mr. Domoto made a trip to Hokkaido, and seeing good possibilities, started an industry which last year produced 190,001 cases of this luscious food.

The total import of Japanese canned crab meat to this country in 1924 was 96,145 cases, of which about 75,000 cases were fancy. Although the United States consumes the bulk of the product, it is now well established in other countries.

Long Beach Community Hospital recently passed the following interesting resolution regarding nurse anesthetists:

"WHEREAS, The California Medical Association has declared that the administration of anesthesia is the practice of medicine.

WHEREAS, The Attorney-General of the State of California has ruled that the giving of an anesthetic is the practice of medicine.

WHEREAS, The Board of Medical Examiners of the State of California has ruled that the giving of an anesthetic is the practice of medicine.

WHEREAS, It is against the spirit of the law, against the ethics of medicine, and against the ruling of a large majority of accredited hospitals for nurses or anyone else not legally qualified to practice medicine to give an anesthetic in California.

WHEREAS, The Superior Courts of two states of the United States have already handed down decisions fixing the liability for damages against hospitals in which nurses have administered anesthetics at the time of the death of the patient while under influence of the anesthetic. Judgments against the hospital to the extent of \$10,000 for damages in one case, and \$150,000 in another case have been obtained.

WHEREAS, The Community Hospital of Long Beach intends to comply with the spirit of the laws of the State of California, the code of ethics of the American Medical Association, and all the requirements for an accredited hospital; therefore, be it

RESOLVED, That the administration of general and local anesthetics in the Community Hospital of Long Beach be limited and restricted exclusively to Doctors of Medicine, (M. D.'s) legally qualified to practice medicine and surgery in the State of California."

Motion made by Dr. J. Scott Brown, seconded by Dr. Frank M. Mikels. Passed August 21, 1921.

"Angered because his fractured arm failed to mend rapidly enough to suit him, a patient went to the Stanford Neuropsychiatry Clinic and seriously injured Dr. Edward F. Stadtherr.

"I intended to kill the doctor," the sick criminal confessed. "He was just experimenting on me."

Of the hundred or more major administrative units of the national government, at least thirty are concerned directly or indirectly with some phase of the public health. These bureaus or other divisions are scattered through the ten executive departments and the score or so of independent establishments of the United States. Generally speaking, they carry on their activities more or less independently.

The first important congressional enactment to deal with health was a law of 1798 that authorized collectors of customs to collect 20 cents a month from each American seaman on merchant ships arriving from foreign ports, in order that medical relief might be given to those needing it. Out of this activity grew the Marine Hospital Service, though it was not definitely organized as such until 1870.—Linsley R. Williams (Journal A. M. A.).

Another argument against advertising is the fact that the majority of advertisements appearing over the signatures of doctors are of men who are neither an honor to their profession nor worthy servants to their communities.

This argument holds. We who have pride in our calling of advertising, and believe some honor attaches to it, are in hearty agreement with the medical men in this particular instance.—Amos Stote (Printers' Ink).

Changes in Health Officers Announced by the California Board of Health:

Dr. Aleck P. Harrison is now Health Officer of Santa Barbara County, succeeding Dr. G. S. Loveren. Dr. Harrison devotes full time to the duties of his office. He is not a member of the C. M. A.

Mr. Frank A. Nikirk is Health Officer of San Leandro, succeeding Dr. Luther Michael. What a commentary!

Mr. C. C. Johnson is Health Officer of St. Helena, succeeding Mr. M. P. Guyon. Mr. C. B. Arditto is Health Officer of Jackson, succeeding Mr. E. Marcucci.

And we talk of health progress!

A. M. A. Requirements for Accredited Hospitals Modified—The Council on Medical Education and Hospitals of the A. M. A. on October 18, 1925, modified the requirements relating to who may practice in an accredited hospital to read as follows:

"In order to receive and retain a position among hospitals approved for the training of interns, a hospital should admit to its staff only reputable physicians who obtained their medical training in, and secured the degree of Doctor of Medicine from, a medical college determined as acceptable by the Council on Medical Education and Hospitals of the American Medical Association. This ruling must be enforced for every person permitted to treat the sick in the hospital or in any of its departments except by nurses, masseurs or other like assistants when acting under the orders of a physician on the regular staff of the hospital. Wherever, because of legislative enactment, public officials deem it necessary to provide hospital facilities for practitioners other than graduates of reputable medical schools, then these should be in a building or buildings which in every way are separate from hospitals for physicians and bearing different names."

The enforcement of this regulation will draw the line of demarkation between cultism and scientific medicine as sharply for hospitals as it has long since been drawn for physicians. However conscience-disturbing the fact may be, physicians do not object to cult hospitals built and managed by cultists for cultists, *when they are so labeled*. It is logical to believe that, were the osteopaths, chiropractors and other cultists honest in their claims of superiority for their various methods, they would be delighted to specifically name and operate their own hospitals rather than being constantly active in attempts to attach to and become part of the educated medical profession and its agencies.

Under this new ruling, supervisors in charge of county hospitals and others whose jobs are so politically uncertain that they are willing to trade with cultists by giving them equal rights with physicians in their hospitals are given a choice of the usual horns of a dilemma. The line of demarkation is clearly drawn, and political units that are in the hospital business for the poor who cannot help themselves and, therefore, must take such services as offered them, can have as many cult hospitals as they want, provided, of course, that they name them separately and make them separate entities, physically and in service, from the hospitals utilized as agencies of scientific medicine.

The cult hospitals will not, of course, receive any form of credit or recognition from educated physicians officially or personally.

In addition to this, it is, of course, as unethical for an educated physician to patronize a cult hospital as it is to share offices or consult with cultists in his private practice.

Again, these decisions are not made for the purpose of fighting cultists, but for the purpose of labeling goods—as we label them under the pure food and drug law—for what they are.

Not a month goes by without seeing litigation between the physician and his patient, with the latter charging the former with negligence in some method of treatment The alleged misuse of the x-ray forms an increasingly large class of this kind of litigation.—A. M. Harris (Medical Times).

Several of our physicians whose names appear in "Who's Who In America," published every two years by A. N. Marquis & Co., 440 Dearborn Street South, Chi-

cago, have been misled recently by a request for a revision of submitted proof copy which, upon casual reading, may appear to be from the editors of this widely used publication.

Careful reading shows the letters and proof to be from "Who's Who Publications, Inc., 799 Broadway, New York City, a different concern, who are putting out a "Who's Who in American Medicine," or at least that appears to be the last name for the proposed volume.

This matter was treated editorially in the Journal of the American Medical Association (October 17), and this additional information is supplied for those interested.

Dosurine—We have given the advertisement of this substance very careful consideration. The opinions we have been able to get seems to indicate that it will do all that its promoters claim for it. It makes the question of routine urine examination, for at least two of the more usual and important possible ingredients, an extremely simple and easy matter—so simple, in fact, that the editor was skeptical about it for a considerable time.

We would be glad to hear the experiences of doctors and laboratories with this substance.

Christmas is so near that we are sure all our readers will be interested in the announcement of the new gift and stationery store of That Man Pitts in the advertising pages of this issue. Mrs. Pitts, who is now conducting the business of her late husband, who was well known to many of you, is so confident that she has a service that will appeal to doctors and their families, hospitals, nurses, and other readers of CALIFORNIA AND WESTERN MEDICINE that she has contracted for paid space for a year in which to make her announcements. The new store at 882 Market Street, San Francisco, is very attractive, and you will find there Christmas cards that are unusual and distinctive, as well as a large selection of gifts.

In succeeding issues this firm will tell you more about the high-grade stationery and office supplies they have to offer at all times. As this is something we all must have, it will be very easy to show our appreciation, in a substantial manner, of the co-operation and confidence Mrs. Pitts has shown in helping support our magazine. Telephone Kearny 8052, and a representative will call on you.

The Vital Capacity of the Lungs in Pneumonia—

A study made by John H. Arnett, Philadelphia (Journal A. M. A.), of the vital capacity in thirty-two cases of pneumonia, delayed resolution and empyema, yielded the following data: In pneumonia the vital capacity is greatly reduced early in the disease. The determination may, therefore, be of distinct diagnostic value in doubtful cases. The greatest reduction generally occurs shortly before the crisis. The advent of the crisis may, therefore, at times be predicted in advance. Cases of uncomplicated pneumonia almost constantly exhibit a rapid rise in the vital capacity in the first five to ten days from the crisis. Patients with empyema and delayed resolution do not exhibit such a rapid rise. The vital capacity may, therefore, assist in diagnosing empyema or unresolved pneumonia. The vital capacity increases gradually for months after clinical recovery from pneumonia or empyema has occurred. In many cases it probably never entirely returns to normal.

Non-specific Granuloma of the Intestine Causing

Intestinal Obstruction—The case reported by T. Homer Coffen, Portland, Ore., (Journal A. M. A.), suggested a tumor mass resembling tuberculosis or new growth, causing intestinal obstruction. The patient has been under observation for nine years, in which time there have been three operations for granulomatous tumors, causing intestinal obstruction. He was fairly well in the intervals. The first granulomatous obstruction followed an operation for appendicitis, subacute. Subsequent granulomas were associated with systemic evidences of focal infection (sciatica, arthritis, low-grade fever, etc.). The last operation showed coincidental suppurative cholecystitis, and the excised tissues and gall-bladder gave a pure culture of streptococci.

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
W. T. McARTHUR, M. D.....President-Elect
EMMA W. POPE, M. D., San Francisco.....
.....Secretary and Associate Editor for California

1926 ANNUAL SESSION, C. M. A. OAKLAND, APRIL 26 TO MAY 1

The Arrangements Committee wish to remind the members of the California Medical Association that the next annual meeting of the Association will be held in Oakland, April 26 to May 1, inclusive.

The State Council has rearranged the program for this meeting. Two days, Monday and Tuesday, have been selected for the holding of clinics, and the Program Committee are inviting prominent Eastern medical men to conduct these clinics at the different hospitals in Oakland.

These clinics will be interesting and instructive and worth your while to attend.

General sessions will be held on Wednesday, Thursday, Friday and Saturday mornings, and the Section sessions will meet in the afternoons of these same days.

All papers presented at this meeting are to be reviewed by the Program Committee previous to presentation, and the number to be presented is to be reduced.

The clinicians who conduct the clinics on Monday and Tuesday are to read papers at the General Session on Thursday morning.

Special attention is being given to the social features of the program. A golf tournament, to be conducted by the Northern California Medical Golfers' Association, will be held on Monday and Tuesday afternoons. All are invited to participate in this event. Many trophies are to be awarded.

Among the other forms of entertainment will be luncheons, boat and auto rides, teas, receptions, dinner dance, and athletic features.

Mark the date on your calendar and make a special effort to attend. We promise you a good time.

(Signed) CLARENCE A. DE PUY, M. D.,
Chairman of Arrangements Committee.

HISTORICAL DATA DESIRED

Dr. Emmet Rixford, chairman of the Committee on the History of the California Medical Association, has sent the following letter to all county secretaries. Will each member of the California Medical Association appoint himself a deputy committeeman to assist this very important committee in collecting material and data?

To All County Secretaries:

The Committee on the History of Medicine of the California Medical Association is greatly desirous of collecting all printed matter extant on the subject of the history of medicine in California for deposit in some safe place where it will be made accessible to students of local medical history. It is urged that the secretaries of the county medical societies undertake, as deputy committeemen, as it were, to interview all of the older men in the profession, or their families or successors, who might have old California medical journals, pamphlets, photo-

graphs of local medical men or hospitals, etc., and forward to the office of the association (California Medical Association).

It is further suggested that each secretary arrange with some member of his county society to prepare a paper on the local medical history or to gather data which the memories of the older man may have retained of events of medical importance, such as founding of hospitals, of local medical societies, etc., etc., contributing the same to the committee, who will arrange for publication of the material as occasion offers. Very respectfully,

EMMET RIXFORD, *Chairman.*

C. M. A. OFFERS PRIZES FOR BEST MEDICAL ESSAYS

At the 148th meeting of the Council, held at Long Beach, November 8, 1924, it was

RESOLVED, That two prizes of \$150 be established—one for a paper on original research, and one for a paper on a clinical subject; and that these prizes be open to the members of the C. M. A. only, and be competed for at the 1926 convention; and, further, that the scope of the material be determined by the committee.

The following committee was appointed: Albion Walter Hewlett, chairman; Dudley Fulton, M. D., 523 West Sixth Street, Los Angeles; and Fred Fairchild, Woodland.

On Doctor Hewlett's resignation, due to illness, Walter C. Alvarez was appointed chairman. The committee regrets that the time for careful work is unavoidably so limited this year.

The accompanying rules for the submission of competing papers have been approved by the Executive Committee:

Rules for the Submission of Papers

1. Any member of the California Medical Association is eligible to compete for the prizes. Any question arising as to the eligibility of a candidate or the admissibility of his essay will be settled by the decision of the Council.

2. Manuscripts must be typewritten on one side of the paper; they must be double spaced; and they must not be folded or rolled. Illustrations or charts must be marked with the title of the paper to which they belong.

3. Essays must contain not more than 4000 words. In judging a paper, the committee will take into account the basic importance of the work done and its novelty; the thoroughness with which the research has been carried out; the clearness with which it has been written up; and the neatness of the manuscript and illustrations.

4. Papers should be sent, preferably by registered mail, to Dr. Emma Pope, Secretary of the California Medical Association, 1016 Balboa Building, San Francisco. They should be identified by a nom de plume or motto only. A separate envelope should be sent to Dr. Pope containing the author's name and his nom de plume or motto, so that after the award is made the name of the writer can be found. Any return addresses or other distinguishing marks will be removed from the wrappers before the papers are turned over to the judges.

5. All papers must be in the hands of Dr. Pope before March 15, 1926, in order that the judges may finish their work in time for the meeting of the association.

6. The judges reserve the right to withhold the award, in the event that no paper comes up to the standards of excellence which they feel should be set.

7. If, in the judgment of the editor of CALIFORNIA AND WESTERN MEDICINE and the Editorial Councilors, the paper on laboratory research is too technical or otherwise unsuitable for inclusion in CALIFORNIA AND WESTERN MEDICINE, the prize winner will be allowed to publish it in some special journal and will be required to make an abstract for the readers in California.

8. Inquiries relative to the prize contest should be addressed to the chairman of the committee, Walter C. Alvarez, 177 Post Street, San Francisco.

A PLEA FOR A KEEN AND ACTIVE INTEREST IN THE CONTINUED ARMS OF THE UNITED STATES ON THE PART OF THE MEDICAL PROFESSION

Should the United States ever become subjected to the commands of an insolent foe it will be because physicians do not now take their places and do their duty in the organization of our country's man-power.

It is hardly too much to say that there is not a single physician in this glorious country of ours who would not instantly drop his own affairs, and hurry with justifiable pride to a sick President if called.

Is not the President the Commander-in-Chief of the Services, and should not the civilian physician prepare himself to efficiently aid the President in his determination to defeat a foe and by that defeat to protect the people and fortify the nation's place in the security of the world?

I maintain that there is no essential difference between the doctor's duty in the welfare against the enemies of an individual and his larger responsibilities as Medical Reserve Officer in aiding the body politic.

Men of high knowledge of war recognize that organized medical experience is absolutely imperative for quick mobilization and for quick demobilization. As a matter of fact, much of the effectiveness in all branches of military service rests upon the wise utilization of the medical, surgical, and dental knowledge of our profession.

This professional learning must, for its full advantage, be correlated with training directed toward a realization of the specific processes associated with the conduct of war. This realization can only be gained by attending a school of military methods conducted by those who know, and this has been made easy by correspondence and adequately supported training camps.

It follows that it is the plain duty of any patriotic medical man to willingly, and without propaganda, apply for a commission which is, in every truth, the gateway to this consummation.

Another way of looking at this and emphasizing the national duty of the doctor is to define the creation of an army under four heads:

1. *Pre-mobilization*—a state wherein the medical men of the country, in time of peace, strive in a selfless way to bring health to the community and by experimentation and persistent effort advance new methods of protecting the individual so that he, when called upon, will present himself with the maximum physical and mental strength. The weaker ones, by this medical procedure, are also prepared for some duty other than the firing line. During this pre-mobilization period, the special education of the commissioned civilian doctor is attended to by the regular officers of the medical corps and the creation of all varieties of "cog-wheel" units; general hospital, evacuation hospital, etc., etc., are made and ready for installment.

2. *Mobilization*—The quick bringing together of healthy men for fighting and executive purposes and less healthy men adequately to aid in subordinate positions; thus preventing sound men wasted in minor jobs, and the careful registration of pre-existing defects, both mental and physical, in each and every individual called to arms. Thus every man sound or otherwise is by the physician's preparedness given a place in the machinery of war.

And so it comes to pass when war is declared, great portals of entrance are equipped in every conceivable way to rapidly and completely take advantage of the man-power. At the same time the future of the individual soldier is protected by a knowledge of pre-existing conditions, or the absence of them, when a consideration of disability, permanent or otherwise, is demanded. Compare this with the hopeless chaos of 1917, when patriotic civilian medical men hurried uneducatedly to the aid of the nation, and were mortified by their ignorance and their well-meant but misdirected energy.

3. *Demobilization*—Here the great portals of entrance are used as portals of exit, and all the machinery of mobilization is utilized for the welfare of the nation and the man. Justice is given to all, and the maximum restoration of the wounded in mind and body secured.

4. *Post-Demobilization*—a state wherein the civilian commissioned doctor, with his special knowledge of the demands of the service, can protect and direct the health of the people who have served, disabled or otherwise.

And so post-demobilization merges into pre-mobilization and the cycle is complete; and thus, also, the service of the medical profession is rendered in the highest efficiency and becomes worthy of its highest attributes and traditions.

It must be kept in mind that all this service carries with it but little inroad upon the private time of the doctor, and the Defense Law protects him from every other form of military duty other than a call to arms against a foreign nation. With so little to lose and so much to give, it is an amazement to me that the march to commission is so halting and so seeming an evidence of a lack of patriotism.

J. WILSON SHIELDS.

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The regular monthly meeting of the association was called to order by the president, H. B. Mehrmann, October 16 at 8:20 p. m. The program was presented by the staff of the Samuel Merritt Hospital. In their program they aimed to point out recent advances in medicine. It was snappy and instructive. A maximum of nine minutes was allowed each speaker.

Robert A. Glenn, in his paper, "The Administration of Glucose in Combating Toxemia," outlined the physiology of the metabolism of glucose and the role played by that substance in body maintenance. The relation of the oxidation of glucose to disturbances of the functions of the liver, kidneys, and other organs was described. An estimate of the quantity of glucose necessary for the body at rest and at work, and of the amounts that might be administered intravenously, which was the method of choice. Certain precautions in the preparation of the solution were given, as well as a simple technic for the sterilization of such solutions.

Frederic M. Loomis read a paper written in a somewhat facetious vein on "Delirium Operatorium," a clever phrase of De Lee's, defined as "an acute lapse of operative reason which may affect the accoucheur after much loss of sleep, the nervous wear of a prolonged labor, the exactions of the family, combined with the sudden appearance of extraordinary difficulties." It was pointed out that birth injuries are much more frequent than supposed, especially in breech cases, and that these injuries are more often due to haste and panic than to essentially impossible situations. The writer urged more deliberation in pelvic maneuvers, and more gentleness in management—"not to mention those lofty souls who disdain any management except the selection of a solid place to brace their feet."

A. C. Siefert gave a brief essay on "Cholecystography," as originated by Graham and his associates. He discussed the theories and facts upon which the method is based, as well as the criteria of normality and pathology of the gall-bladder when examined by this test. He concluded that cholecystography is a great step in advance of the ways of roentgenological examination of the gall-bladder hitherto used, and that the oral administration of the dye is sufficiently safe to be used routinely.

A. A. Alexander discussed differential diagnosis of organic and functional heart disorders. Many heart conditions, he said, are classed under "myocarditis." This diagnosis should be made with care. Myocarditis is an element in a pancarditis in such conditions as rheumatic fever and syphilis, whose organisms invade the heart, but in most febrile conditions the cardiac muscle is damaged by circulating toxins, rather than by inflammatory changes. By means of case report he pointed out the apparent identity of symptoms in functional and organic disorders. Then taking up the symptoms separately, he indicated differential considerations. Many patients, he said, with or without actual heart disease, readily develop a fear neurosis or "cardiophobia," and in this connection deplored the tendency to stress to the patient the existence of cardiovascular findings, such as murmurs or alterations in blood pressure. In organic heart disease treatment, in his opinion, cannot effect a cure. One must consider (1) the avoidance of further damage by removing obvious infection; (2) adjustment of the patient's habits of life and work to his heart reserve, rather than attempting to fit the heart reserve to the patient's

effort; (3) the use of drugs, if heart failure threatens. Functional disorders tend to relapse, but do best with hygiene and suggestion to rebuild the patient's confidence.

In an analysis of twenty patients, the following conclusions were noted by Francis Shook in his paper, "Maxillary Antrum Infection in Children." (a) The symptomatology is local and general. The most frequent local symptomatology is (1) impaired nasal respiration, (2) frequent coryza, (3) mucoid discharge, usually post-nasal, (4) "crusting" in anterior nares, with sneezing attacks on attempts to dislodge the crusts by sniffing, (5) bronchitis or night coughing caused by post-nasal dropping into the bronchi. (b) General symptomatology—absorption from the chronic infection causes the general symptomatology. In order of frequency, the following has been noted: (1) The child is below par in strength and usually in weight; (2) pyelitis and cystitis; (3) beginning degeneration, such as myocardial; (4) occasional myalgia (growing pains) tenderness at tendon insertions, joint involvement (rare); (5) occasional febrile attacks. Treatment—The most satisfactory combination has been (1) infratubinal drainage of the maxillary antrums under nitrous oxide or ether-vapor anesthesia, (2) after treatment of antrums—suction, lavage, vaccine, anilin dyes (acriflavine or gentian violet), (3) hygienic and dietetic supervision by family physician or pediatrician.

C. L. McVey spoke on the "Present Status of Intravenous Dye Therapy in Septicemia," and drew inferences from Hugh Young's report on 210 cases.

In his subject, "Fallacy of Easy Sterilization of the Urinary Tract," E. Spence DePuy discussed the newer urinary antiseptics, devoting special consideration to hexyl resorcinol and mercurochrome, in particular. The writer called attention to the widespread desire of all for some easy method of sterilization of the urinary tract; one that would free the urine of pus, and relieve the patient of the symptoms attendant upon infection—an antiseptic that required possibly no investigation of the patient's condition and which might be self-administered. Desirable as such easy therapy may be from the viewpoint of both physician and patient, however, the paper pointed out that, with such agents as are at present available, simple administration of drugs, either orally or intravenously is generally not sufficient to sterilize the urinary tract for the two following reasons: (1) Many urinary tract infections are secondary to distant foci. (2) The more severe urinary tract infections are frequently the result of obstruction, either in the urethra, at the vesical neck, in the ureter, at the kidney pelvis, or in the kidney itself. Obstructions cause a residual or stagnant urine. Stagnant urine is a favorable culture media. To secure sterilization of the urinary tract, then, requires that focal infections be eliminated and that obstructions be overcome. It was then pointed out that the natural inference is that nothing, so far discovered, has taken away the necessity for investigation and diagnosis. And that in the case of mechanical obstructions, ureteral kink, stricture, etc., it is not so much the drug that is employed, whether by mouth, intravenously, or even by instrument to the infected part, as it is to the relief of obstruction by instrumentation, plus all the known urinary antiseptics—mercurochrome, hexyl, resorcinol, and nitrate of silver solutions.

M. L. Emerson's subject was "Carcinoma of the Bowel." He presented two of his six patients, pre-operative pictures, also lantern-slide demonstrations of the operative technique. He stated that, by deperitonizing the bowel tumor before removing the same, there is eliminated the much-dreaded peritonitis so frequently complicating this type of work, and the operative mortality was greatly reduced. By circumscribing or walling off the growth with the peritoneum, practically placing the growth outside of the abdominal cavity, it facilitated and made visual the application of radium and x-ray. Where it was possible to mobilize the growth, the tumor mass and bowel was lifted out of the abdominal cavity and deperitonized around the loops of the bowel, the tumor being removed a few days later, thereby shutting off the abdominal cavity much after the fashion of Mikulicz's operation. The cancerous growth is then removed a few days later, and further application of radium or x-ray, if thought necessary. By the application of radium, x-ray and surgery, we have been enabled to make these patients fairly com-

fortable, and some of them over a period of three years. The doctor also stated that Crile and other operators have reduced the operative mortality of this type of work down as low as 2 per cent by using the several-stage operation.

In his brief discussion of "The Present Status of Radium and X-ray Therapy," W. H. Sargent stated that when the best interests of the patient are considered, radiation therapy is neither a substitute nor competitive of other therapeutic measures, but a valuable adjunct to both surgery and medicine, and in advanced malignancy it is the greatest palliative so far known. In early cases he deems it inadvisable to attempt a cure with radiation when the disease can be completely removed surgically. In cancer of the breast with glandular involvement, he believes a more thorough trial of pre-operative radiation seems justifiable, since surgery alone can offer so few chances of cure. Sargent also believes that greater co-operation between physician and radiologist is much to be desired, and will undoubtedly be productive of better results.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the Contra Costa County Medical Society was held at the offices of Drs. Abbott and Hely at Richmond, October 31.

The lecture was delivered by Hans Lisser on the pathology, diagnosis, and treatment of ductless glands, illustrated with lantern slides. The lecture was classical. This is Dr. Lisser's third lecture to the Contra Costa Society in eighteen months; the attendance was up to the standard. The unanimous verdict of the members present was that they wanted Dr. Lisser again. This we consider very complimentary to him.

The following members were appointed by the president to arrange for the annual meeting to be held this month to elect officers for the ensuing year: L. M. McCollough, S. N. Weil, L. H. Fraser.

The following members were present: C. E. Camp, San Pablo; G. M. Bumgarner, J. W. Bumgarner, H. L. Carpenter, P. C. Campbell, L. H. Fraser, Denninger-Keser, U. S. Abbott, L. St. John Ely, Rosa A. Powell, Hall Vestal, Richmond; John and Mrs. Beard, Martinez; T. W. Lavery, University School of Medicine; F. L. Horne, J. M. McCollough, William A. Rowell, Crockett; J. T. Breneman, El Cerrito; S. N. Weil, Selby.

FRESNO COUNTY

Fresno County Medical Society News (reported by J. A. Montgomery, secretary)—The Fresno County Medical Society has begun a campaign for diphtheria immunization.

On October 17, Dr. Halliday of the State Board of Health addressed the Medical Society at a luncheon-meeting. He demonstrated the technique of the immunization by giving several first treatments to children from the schools. He also discussed the work being done in California counties, as well as that that has been done in New York City.

Dr. Matthewson of the Fresno City Board of Health outlined a plan whereby this work should be done as completely as possible by the physicians in their own offices, urging their families to come for this work to their own physicians. He is conducting a campaign of newspaper publicity toward this end, and the city schools are sending out pamphlets of information to all homes. Physicians in the county are urged to report to the City Health Office the number of children receiving treatment.

It is the intention of the society in this campaign to avoid the use of the general free clinic for this purpose, and to confine the free treatment to those applying to the County Hospital Clinic and found entitled to charity.

A meeting of the Fresno County Medical Society was held on November 2. Dr. James Percy of Los Angeles gave the address of the evening. His subject was "The Treatment of Cancer." He discussed the methods of use of the cautery, the proper manner to use the cautery, and demonstrated some of the cauteries used in this work in his own practice.

At this meeting Edwin Mott, Charles Fulmer, and Edward Halley were elected to membership in the society.

HUMBOLDT COUNTY

Humboldt County Medical Society (reported by L. A. Wing, secretary)—The following meetings of the Humboldt County Medical Society were very much enjoyed by a large attendance of the members. The June meeting was held in Ferndale, as guests of Doctors Brunner and Ring. Papers were read by Doctor Brunner, on "Diabetes," and Doctor Ring on "Treatment of Burns."

The July meeting was held in Scotia, as guests of Doctors Cottrell and Haight. Papers by Doctor Cottrell on "Injuries to the Spine," and Doctor Haight on "Pleurisy With and Without Effusion," were read.

On October 6, a meeting was held in Eureka. Doctor Charles C. Falk entertained the society with a very enjoyable talk on his experiences with the medical world while abroad.

MARIN COUNTY

Marin County Medical Society (reported by John H. Kuser, secretary)—A meeting of the Marin County Medical Society was held on October 29 at Doctor Jones' office in San Rafael. The following members were present: Frank Cannon, O. W. Jones, W. F. Jones, L. L. Stanley, G. M. Landrock, and J. H. Kuser. The secretary was requested to send to the A. M. A. for twenty copies of "Principles of Ethics," to be distributed among the members. Notes taken by Dr. Kuser, Health Officer of Marin County, at the Health Officers' meeting at Long Beach were read and considerable interest was shown by a lively discussion. The necessity of co-operation of the organized profession to control and prevent disease was well brought out.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by Bert S. Thomas, secretary)—The local society convened at the Sacramento Hotel on the evening of October 20 for its regular meeting. In addition to twenty-two members, the society was treated to a visit from the entire State Board of Medical Examiners, who, at the time, were met in their yearly Sacramento session. Those attending were Phillips of Santa Cruz, the president; Brown of Los Angeles, the vice-president; Pinkham of San Francisco, the secretary; Brem and Smith of Los Angeles, Morton of San Francisco, Harris of Sacramento, Yates of San Diego, and Adams of Oakland.

The minutes of the September meeting were read and approved.

Case Reports—Dillon reported a case of a complete right pneumothorax. The boy had fallen and had lacerated a small area mesial to the right shoulder. In a short time air had filled the entire right chest cavity. X-rays of the condition on the sixth day were presented.

Gundrum reported a case of a man whom he had referred to Green. Despite the fact that there was neither impaction nor any pathology of the tooth-bud, a fully grown tooth had not come in to take the place of a deciduous one. These two reasons are the only ones to explain the lagging of a fully formed tooth. No explanation could be offered for its lack of descent.

The paper of the evening, "Infant-Feeding—A Survey," was presented by Edward S. Babcock. He said:

"Infant-feeding is one of the most important branches of medicine, but, unfortunately, is one of the most neglected. Our high infant mortality rate is due to a lack of instruction, or improper instruction to mothers, in the care and feeding of infants. Infant welfare centers throughout the country have played an important part in decreasing the infant death rate.

Obstacles to breast-feeding, and methods of overcoming them, are discussed. Manual expression of the breasts is advocated to increase a failing milk supply.

The history of the development of artificial feeding from the time of Biedert, Liebig, and Rotch to the present time were given.

Water, proteins, carbohydrates, fats, salts, vitamins, and acidity of cow's milk were discussed in turn. The known methods of modifying, changing or substituting each were given. Proprietary infant foods, largely carbohydrates, are grouped into simple sugars, dextri-maltose compounds,

and preparations containing more or less starch. Preparations advertising direct to the laity are a menace to public health. A boiled cow's milk, water and Karo syrup mixture, correctly proportioned, is advocated for routine feeding, because of simplicity in preparation, convenience and cheapness.

Computation of caloric values and examinations of stools were discussed as important checks on the feedings.

Mixed feeding was discussed briefly. Feeding of premature and sick infants is not considered in this paper. The so-called difficult feeders are considered medical cases and should receive special attention. Many of them are found to have a pyuria, otitis media, or congenital abnormality of some nature.

Intolerance to various food elements and allergy were briefly considered.

Dental caries, malocclusion of the teeth, speech defects, chronic constipation, smallpox, diphtheria, and many other infirmities of later childhood and adult life could be practically eradicated if all mothers were properly instructed in infant-feeding and care."

In the discussion, Pitts discussed the possibilities of galactagogues. Pitts believes that it is possible to measurably run up the quantity of milk in twenty-four hours. Gundrum added that, without any question, he believed beer to be a definite galactagogue. He related how Stephanson had told him of types of infant-feeding in the Antarctic. Most of the mothers chewed up meat and then fed it to their babies. It was really remarkable how they thrived. Hall told of Health Department methods in the control of the local milk supply.

In closing, Babcock stated that extensive experimentation had been conducted in Chicago on the possibilities of galactagogues. Their final conclusions, based on the most careful measurements, show that there was no galactagogue among the great number of supposed ones. Regarding the question of goat's milk, Babcock declared that this contained too much fat and salt. He also added that, despite the fact that he carefully follows the Health Department reports, he uses boiled milk in his infant formulas.

Brief remarks were made by all members of the Medical Examiners. Several spoke directly on the paper of the evening. Yates, as a dermatologist, has one feature connected with goat's milk—eczema. Harris and Smith, both of whom had returned from their recent trip through England and Ireland, told of the pathetic condition of the cattle in Ireland, where whole flocks were definitely tuberculous. The results can be seen on all sides.

Applications for Membership—The applications of Norris R. Jones, Angus A. McKinnon, and Joseph L. Mullin were read for the first time. After the second reading of the applications of Clyde G. Reynolds, Edward P. Moser, Hans F. Schluter, and Charles I. Titus, a vote was taken. All were unanimously elected to membership in the local society.

Report of the board of directors announced a paper by G. Parker Dillon, concerning diagnostic problems of the rectum at the November meeting.

Communications—One from Colonel Edward L. Munson was read, thanking the local society for their sponsoring plan of the M. O. R. C.

State secretary's note calling attention to the resolution concerning the submitting and approving by the Program Committee of the State Society of all papers to be read by any member of the association at any annual meeting, and the space to be given them in CALIFORNIA AND WESTERN MEDICINE, was read.

A letter from Dr. Leo P. Bell, asking the local society to be one of several societies to present a film, entitled "How the Fires of the Body Are Fed," was read.

An invitation from City Manager Bottorff to visit the city's filtration plant was considered under new business. The invitation was accepted, with the suggestion that some night be named for the inspection.

Motion was made, seconded, and carried that the local society join with Woodland, Chico, Red Bluff, Redding, and Stockton in the public presentation of the film, "How the Fires of the Body Are Fed." The meeting adjourned to the banquet table.

SAN FRANCISCO COUNTY

Franklin Hospital Clinical Society (reported by Ewald H. Angerman, secretary)—The Franklin Hospital Clinical Society met at the hospital on October 5, J. Wilson Shiels presiding.

Dr. Westerfeld reported a case and discussed the subject of "Echinococcus Cyst of the Liver." Dr. Schaupp's subject was "The Heart in Pregnancy."

St. Luke's Hospital Clinical Club—St. Luke's Hospital Clinical Club resumed its regular meetings on Thursday, November 5, the speaker of the day being Clement H. Arnold. His subject was "Some Interesting Cases of Congenital Heart Disease." He stated that although the chief interest of congenital abnormalities is to the embryologist and pathologist, and the greater number of cases occur in children, yet it had been his good fortune to have seen several cases in adults. Persistence to adult life makes the recognition and treatment of congenital heart disease of some moment, particularly in the management of the patient's life and our ideas of prognosis.

His talk was illustrated with drawings demonstrating embryological development of heart and blood-vessels and abnormalities resulting from such lack of development. He presented the history of four very interesting patients which had come under his observation—one with pure dextrocardia and anomalous electro-cardiogram; another of combined mitral stenosis, patent interventricular septum and bifid apex which came to autopsy; a third of patent interventricular septum which came to autopsy, and the fourth of patent ductus arteriosus. These adults ranged in age from 35 to 62.

The speaker outlined the main phenomena by which the presence of congenital malformations could be recognized, following this with a short axiomatic recapitulation of cardiac symptoms and findings, as related to congenital heart disease, summing up with the statement that the presence of congenital defects in any other part of the body is in favor of any heart affection present being congenital.

St. Joseph's New Buildings—Variable Staff Program—St. Joseph's Hospital of San Francisco has begun its extensive fireproof reconstruction by demolishing its older structures, in preparation for the new units, which will provide 200 patients' beds and for 150 Sister and lay nurses and other attachés and incorporate the latest ideals in hospital construction. All of the patients' accommodations will be maintained until after the rebuilding, when the last of the present structures will be torn down, making way for others planned.

The staff met on November 18 and enjoyed a varied program based on recovered cases from the hospital. P. Collischonn spoke of the "Talma Operation" and outlined a case where abdominal ascites was permanently relieved, after previous repeated tapings. D. E. Stafford discussed "Ectopic Pregnancy," illustrating it with a recent case. J. C. Newton read a paper on "Dermoids," describing a case of double unilateral lesions in a girl. "Medical Notes From the East" were given by T. I. Janes, and included observations with Farr, the Mayo staff, and Crile. W. T. Cummins, pathologist, differentiated teratoma and similar tumors, and Lloyd B. Crow, radiologist, showed mediastinal x-ray films.

A. S. Musante, head of staff, offered resolutions respecting the death of Doctor Albion Walter Hewlett, Professor of Medicine at Stanford University, who was on the consultation staff of St. Joseph's and had addressed the meeting recently on post-operative medical treatment. William Quinn and Howard Dixon presented case histories of patients with pneumonia and gas phlegmon of the neck, respectively.

The program of December 9, "Pediatric Night," follows:

"Advances in Pediatric Diagnosis," C. F. Gelston; "Modern Treatment in Children's Diseases" and "Surgical Considerations in Pediatrics," Emma Willits.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by P. C. Means, secretary pro tem.)—The regular meeting of the Santa Barbara County Medical Society met in the staff room of the Cottage Hospital November 9. President F. R. Nuzum introduced Willard J. Stone, of Pasadena, who presented a very careful and interesting

paper on "Certain Aspects of Heart Disease, Including Coronary Occlusion, Angina Pectoris, and Adhesive Pericarditis." Free discussion showed the interest with which it was received. Harry L. Schurmeier presented a patient who had had, some months ago, trophic ulcerations on the toes and had been cured at a Southern "sanatorium" by starvation for two weeks and rest in bed. The patient was much impressed, and said there was explained to him "the harm of combining vegetable and animal proteins." The dangers of starvation and the temporary value of rest were pointed out in the discussion, but did not shake the faith of the patient.

✽

YOLO-COLUSA COUNTIES

Yolo-Colusa County Societies (reported by John D. Lawson, secretary)—October 16—Regular quarterly meeting in conjunction with Woodland Clinic conference.

Amendment to the constitution was proposed, changing the name of the society from Yolo County Society for Medical Improvement to the Yolo-Colusa County Medical Society. This will be voted on at the next regular meeting.

Program—Observations on recent trip in the Middle West and East, by John D. Lawson. Presentation of a case of diabetes with lipemia retinalis and xanthomata diabeticorum, by J. Edward Harbison. Differential diagnosis in an upper abdominal tumor, by Leo P. Bell.

Russell G. Frey, resident physician at Woodland Clinic Hospital, was elected to membership in the society. Walter J. Spencer, member of the staff of the Woodland Clinic, has severed his connection with that institution. He expects to enter into the practice of pediatrics in the southern part of the state.

Fred R. Fairchild has just returned from a month spent in the Hawaiian Islands.

H. D. Lawhead, Yolo County Health Officer, reports a rather unusual amount of diphtheria in the county, notwithstanding a concerted effort toward the popularization of toxin-antitoxin prophylactic.

The public lectures given monthly by the Woodland Clinic were resumed in October, when Dr. H. D. Lawhead spoke on "The Doctor of Forty Years Ago and Today" With Some Personal Reminiscences."

At the November meeting Dr. J. Edward Harbison spoke on "Various Types of Infectious Diseases, Their Prevention and Treatment." This was illustrated by a moving picture, entitled "How Disease is Spread."

Woodland Clinic—The directors of the Woodland Clinic have authorized the construction of the first unit of a new hospital building, and construction is to begin immediately. The new unit is to have a capacity of seventy-five beds, which will be a considerable addition to the fifty-five beds now in use. The building is to be absolutely fireproof, and will incorporate many new features of hospital construction. This will be known as the first unit of a building which, when completed, will consist of four lateral wings with a central administration building. Each wing will cost approximately \$100,000 and the administration building probably twice that amount, so that the completed structure will cost approximately \$600,000. The greater portion of the new structure is to be devoted to actual patients' rooms. Certain portions of the present building will be utilized to give additional space to the various departments, the size of which will necessarily be increased, owing to the addition in the number of patients. The name of the corporation has been the Woodland Sanitarium, but owing to the fact that the hospital has always handled general medical and surgical work the title was a misnomer. The entire organization is now to be known as the Woodland Clinic. Consequently, the hospital department will be known as the Woodland Clinic Hospital.

✽

CHANGES IN MEMBERSHIP

New Members—Roger W. Barnes, Ivyl Clare Bedwell, Warren P. Clark, Willis M. Gardner, Wesley J. Hommel, Ralph R. Holzman, Robert W. Langley, Arthur E. Mark, Ihil Rubenstein, Fred McKay Bantum, Edward R. Cox, Los Angeles; Cecil F. Charlton, Pasadena; William Joseph Eckerle, Wilmington; Richard J. Morrison, Santa Monica; Richard C. Rush, San Fernando; Walter Claude Thomas, Long Beach; Solomon N. Weil, Selby; Elwyn H. Welch, Pomona; Preston W. Whitaker, Van

Nuys; Henry A. Beaudoux, Christopher Howson, Theo C. Lawson, Oakland; Henry L. Charles, Alhambra; Elton Russell Clarke, Burbank; Rupert G. Doupe, Tehachapi; John F. Edwards, Hollywood; Belle C. Eskridge, Monrovia; David Martin Ghrist, Glendale; Sidney Gidoll, Keene O. Haldeman, Harry C. Shepardson, San Francisco; William McKee Moffatt, Santa Barbara; C. O. Petty, Fullerton; Virgil G. Presson, Santa Ana; George Henri Rohrbacher, Stockton; Peter N. Root, Bakersfield.

Transferred—R. C. Burkett, from Los Angeles County to Orange County.

Marshall C. Cheney, from San Francisco County to Alameda County.

Cory C. Ledyard, from Santa Clara County to Los Angeles County.

Frank E. McCann, from Tehama County to Los Angeles County.

G. A. Wislicenus, from San Francisco County to Washington Medical Association.

Resigned—From Los Angeles County: Milton A. Barndt, T. Furusawa, W. W. Murphy, F. T. Nakaya.

Deaths—Hewlett, Albion Walter. Died at Philadelphia, November 10, 1925, age 50. Graduate of Johns Hopkins University Medical School, 1900. Licensed in California in 1903. Doctor Hewlett was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Legault, Joseph William. Died at Oakland, October 23, 1925, age 58. Graduate of Victoria University, Canada, 1890. Licensed in California the same year. Doctor Legault was a member of the Alameda County Medical Society, the California Medical Association, and the American Medical Association.

McConnell, Edward Giles. Died at San Francisco, October 19, 1925, age 57. Graduate of Cooper Medical College, California, 1893. Licensed in California in 1894. Doctor McConnell was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

ALBION WALTER HEWLETT
1874-1925

Doctor Hewlett was born in Petaluma, California, November 27, 1874, and died in the University of Pennsylvania Hospital, Philadelphia, November 10, 1925.

The family early moved to San Francisco. Our first indication of his later achievement is found in an old newspaper article which records his graduation from the

Oak Street School at the head of his class, although he was two years younger than the other members. First honors were again his on graduation from Johns Hopkins Medical School in 1900.

Internal medicine had already marked him for her own, for Dr. Hewlett rejected a surgical internship at the Presbyterian Hospital to accept a medical service at the New York Hospital. After a two-year internship he spent a year at Tubigen. A direct result of his work here was the translation of Krehl's Clinical Pathology. Indirectly, Krehl's influence led to studies which bore fruit in Hewlett's work on Pathological Physiology.

Dr. Hewlett was married in 1907 to Miss Louise Redington. Her sympathetic interest made possible a life of devotion to research, in addition to his clinical and teaching responsibilities.

On his return to the United States in 1906 he was attached to the staff of Cooper Medical College. In 1908 he was called to the chair of Internal Medicine at the University of Michigan, where he remained until his selection as Professor of Medicine in the Stanford University School in 1916. During the war he served overseas with the Stanford Base Hospital Unit, as Lieutenant Commander in the Medical Corps of the Naval Reserve.

Dr. Hewlett's research, with the exception of a few early papers, has been largely concerned with the physiology and functional pathology of the heart and circulation. The series of papers on the blood flow in the arm is perhaps most notable. His primary interest lay in the clinic, and his purely clinical papers cover a wide range of subjects. All his writing is distinguished by a sound conservatism in expressed opinion, and by a refreshing clearness and simplicity of style.

Dr. Hewlett's emotions interfered with his judgments far less than is common among us. The fallacies of his own most cherished prejudices—and those of his friends—were always quite as clear to him as were those of his opponents in discussion; and this resulted in a frankness and honesty which were at times almost amazing. Those who did not know the man may have sometimes interpreted this absence of emotional bias as an indication of an unsympathetic nature, but even a brief association never failed to demonstrate an unusual interest in the problems and enthusiasms of others. Those privileged with still closer friendship can testify to the deep loyalty of his affection.

In the death of Dr. Hewlett, Stanford University Medical School has lost an inspiring teacher; the medical profession has lost a resourceful leader; and medical research has lost an able, enthusiastic worker. H. G. MEHRTENS.

Unperforated Ulcers of Terminal Ileum, Symptomatically Simulating Appendicitis—J. Shelton Horsley, Richmond, Va. (Journal A. M. A.), reports three cases that gave rather clear symptoms of appendicitis and yet were not appendicitis cases at all. They were cases of ulcer of the ileum, two of them being tuberculous. Horsley emphasizes this point: The surgeon who opens the abdomen for appendicitis should be prepared to deal with any condition that he may find. If the appendix is easily removable, the operation requires no great amount of skill; but if there is an ulcer of the duodenum, a diverticulum of the cecum, or some affection more serious than simple appendicitis, the life of the patient is in jeopardy unless the training of the surgeon enables him effectively to deal with these diseases. The obvious treatment for chronic ulcers of the terminal ileum is excision, and excision of an ileac ulcer usually means resection of the bowel.

"Certain professional moralists," said the Rev. Lloyd C. Douglas at the University of Michigan commencement exercises, "would have us believe that the blatant criticism of the movies may be held responsible for much of our moral turpitude which is, of course, arrant nonsense. The movies are not a cause of anything, but a natural effect; for the public has been nourished on the sentimentality of sentiment until only the rudimentary urges of undisciplined physical life remain sufficiently active to be stirred. The superheated fiction of the day, and the raucous squawk of the ubiquitous sex-a-phone are not causes of anything; they are the inevitable achievement of an age that has fed its emotions on red pepper until its jaded palate refuses to react to any dish unless served with nitroglycerine sauce and garnished with firecrackers."

Editorials by J. U. GIESY, Associate Editor for Utah

PETRA—THE ROCK

It is an old saying that the body of man is "founded upon a rock," and recent biochemic investigation and experimentation would seem, in a sense, to justify the old-time assertion literally, rather than figuratively—to show that we are builded upon a rock indeed. For, while not all rocks in the actual sense are of the same chemical formation, certainly lime enters into the chemistry of the formations known as rock to a vastly predominating extent. And the further research goes, the more are we faced by the importance in the body's chemistry of the element calcium.

Calcium balance seems, from all one can gather, to be the very foundation—the rock—of normal metabolism, with the other mineral salts grouped around it. Almost, present-day notions would appear to be a calcium dream. Yet results seem to show that it is no dream, but fact—and a fact which is opening up the doors to a better and more effective understanding of the internal chemistry and the necessary procedures to be instituted when there is a disturbed balance of this most important of all elements to be overcome.

Calcium in the blood in ionic or diffusible form seems to spell the difference between susceptibility to infection; to normal bone development; to the presence or absence of the colloid thyroid degeneration; to normal digestion, with its perversions, as tetany of deficiency origin, spasmophilia, convulsions of a myo-clonic type; to the development and healing of ulceration, to acute guanidin intoxication in infants, and the absence of all these. And the parathyroid gland seems to be the governor of calcium fixation and balance. What a wonderful thing the body in its silent function is. More and more, as we learn the true function and association of the endocrine chain, we will come to be able to play on the very keyboard of life and restore harmony for discord, and so give relief in dysfunction, imbalance, and disease. It is an inspiring thought—one to make the heart of the medical man beat a bit swifter, draw on some of his potassium, magnesium and calcium reserve, for very pride in what may come with the years. Calcium plus sunlight, natural or artificial, activating the blood-contained cholesterol, are already working wonders in the hands of capable men who understand their use. Rickets is being mastered, malnutrition is a condition recoverable in the major per cent. Old ulcerations heal—bronchial and peribronchial conditions yield and give the sufferer ease; anemias clear up and the erythrocytes increase, the whites drop, the blood iron comes up, restoring the true balance of health. Well, Solomon said there was nothing new under the sun, and the ancient Hebrews said man's body was built upon a

stone—and it begins to look as though both enunciations had been right.

THE PUBLIC TROUGH

For God knows how long a certain type of individuals have been trying to put over the trick of getting something for nothing. And sometimes they almost seem to get away with it. In reality, they do not. Nobody does. Always we pay one way or another. But the idea is firmly imbedded in the brains of a few that the trick can be worked.

We refer directly to those individuals who—able to pay for professional service—yet seek to take advantage of the free clinics established for the care of the indigent. If it were not so disgusting it would be rather bizarrely amusing to see these social pirates drive up to a free clinic in their limousines.

It is because of this abuse that recently the president of the Salt Lake County Society appointed a committee to wait on the candidates for election as City Commissioners and gain their views on the matter. It is refreshing to state that each and every candidate unhesitatingly went on record as opposed to this sort of thing.

And they should have—any honest person should. The free clinic is for the humanitarian relief of the sufferer who cannot pay. The person who seeks to get his feet in that sort of a public trough is no better than any other public thief.

POLLY PHAR MACY

Polly is a great girl. She's a sort of siren, not to say vamp. One might almost call Polly a prostitute and not be far from the mark. Polly is largely, we feel, to blame for the fact that prescription-writing is, in a way, to become a lost art.

We don't actually know how far the instruction in pharmacy and therapeutics goes these days in the modern medical college, but conversations had with recent graduates would indicate that it is more or less brief. And yet on therapeutics and its allied application in pharmacy the entire fabric of internal drug employment is based.

And there are only so many drugs—as yet—though what the synthetic laboratories may evolve in the future no one may state. The point we are trying to stress, however, is, that there are only so many chemicals which the tests of time and experience have proved. And that being the case, there are only so many chemicals which can be combined in a therapeutic fashion to produce a pre-judged effect upon disease. Consequently—and this is the crux of the matter—Whosis & Company's Compound, or Whyis Syrup, are each and all compounded of those self-same drugs.

Wherefore, it is rather weird to realize that we of a profession who rave because some lady patient confesses to having taken a bottle of Pydia Linkum's Female Restorative should show such a readiness to prescribe the compound put on the market by the Whosis Company, and never bat a lash as we gracefully sign our name at the bottom of the prescription sheet.

Yet wherein is there so great a difference between the frankly "patent" formula and the "proprietary" pharmaceutical? They are both stock formulas—

they are both pretty much shotguns. They are both certainly incapable of meeting the requirements of more than a certain percentage of individual cases, and they are both compounded from some of the definite number of known and well-tried drugs—drugs the physician should, of course, be familiar with both as to their therapeutic qualities and their indications before he becomes an accredited physician.

And here Polly once more gets in her work, because Polly is the goddess of polypharmacy, and "manufactured pharmaceuticals," like "patent medicines," are in the primary instance made to sell. Wherefore, when Whosis puts out their compound, Whyis and Whatfor and Thatsit, and Company all put out similar compounds to catch what they can of the sale while such compounds are the vogue. And each corporation sends out a flock of detail men to extol the merits of these similar combinations of tried and proved remedies and floods the physicians' mail with literature telling just what this particular compound does.

To the result that the physician prescribing this or that finds himself soon in the position of an unpaid member of the Whosis or Whatis Company's selling and distributing force. And the pharmacist has fifteen bottles on the drug-store shelf, each containing a similar compound marketed under a different but equally fancy name, instead of one bottle of a standard drug. And this, simply because Dr. Why or Dr. What, ad infinitum, each prescribes the same or practically the same thing under the particularly different name of each manufacturer's choice.

Ain't we the damned fools? Of course, the organic iron formulas are, some of them, nice to the taste. Some of these manufactured pharmaceuticals are not bad to take. Yet is "Egg-Iron," as one of the popular brands literally calls itself, or more liberally translated perhaps by intent Iron-Abluminate—any more efficacious really than the Syrup of the Iodide—Blauds—or the N. F. Iron Peptonate?

And isn't it rather time to ask ourselves why we should gratuitously help the manufacturing chemist to sing a paraphrase of Stevenson's oft-quoted lines:

Fifteen bottles on a drug-store shelf.

Yo, ho, ho, and the same stuff in every one!

Isn't it about time that we asked ourselves if it wouldn't be better for ourselves and our patients if we learned to use standard medicaments more and fit the prescription to the patient more exactly? In reality, a prescription should fit like a comfortable shoe or a well-tailored suit of clothes. The doctor's skill lies, of course, in making it fit. But that's the job of the shoeman, the tailor, or the doctor—or none of them has any job.

Isn't it about time that we gave more attention to the nearly lost art of prescription writing, and less to the advertising literature that floods the mails? The wastebasket is the place for most of the latter, and the waste-paper basket is the place for most of the stuff it is sent to advertise. That or the sink. Nowadays almost anybody who has a steady hand to pour from bottle to bottle, and the intelligence to lick a label, can be a pharmacist—insofar as the bulk of prescriptions are concerned. Ain't it the bunk?

Utah Notes (reported by J. U. Giesy)—Alfred Blumberg, Salt Lake, has been appointed to the staff of the United States Veterans' Hospital, Orten, North Carolina. Dr. Blumberg's duties will consist primarily of pathological and research work.

First Lieutenant Leo John Miltner, a physician at the Holy Cross Hospital, has been assigned to the Medical Reserve Corps of the 104th Division and attached to the 413th infantry.

A. A. Kerr, head of the Archaeology Department of the University of Utah, has returned from a trip through the southern part of the state, with three new relics to be added to the ethnological museum of the institution.

Under the direction of Major Samuel C. Gurney, chief medical officer for the 104th division, a school for Medical Reserve officers is being conducted in the offices of the United States Veterans' Bureau on the fifth floor of the Boston building, beginning at 8 o'clock. Meetings will be held every second and fourth Wednesday of each month during the winter.

The class work will consist of lectures and demonstrations on medical and military subjects.

Nearly 100 officers are eligible for the course, including 56 doctors, 24 dentists, 12 medical administrators, and 2 sanitary engineers.

Through the efforts of the parents and teachers of the Bear River City school, about ninety students have just been inoculated for diphtheria.

Ralph O. Porter, dean of the Utah Medical School, is back from the convention of the Association of American Medical Colleges recently held in Charleston, South Carolina. Doctor Porter inspected ten prominent schools of medicine while absent, and feels that the Utah school measures up creditably with any in the country.

J. J. Galligan is back from the convention of the American College of Surgeons at Philadelphia.

F. Leaver Stauffer, wife and family, are in Philadelphia, where the doctor is doing post-graduate work. They will remain for some five months.

F. B. Steel, secretary of the State Association, is in Chicago for a period of some three weeks. During his absence he will attend the meeting of the secretaries of the A. M. A.

Latest advices look favorable for the erection at Salt Lake of a United States General Military Hospital, to cover the necessary service to the ex-service and military men of the intermountain region. This is a long-felt need, and will serve an excellent purpose, as well as take advantage of a wonderful location, both climatically and as regards transportation facilities.

The editor wishes to apologize for the way the editorials in the October issue were printed. As far as he can judge, the compositor was either hopped up or else dropped the galley and pied the works. Parts of two separate editorials were scrambled together with little regard to sequence, and the results, as no doubt noted, were weird.

[Note—I wish to add my apology to that of Doctor Giesy for this blunder by the printers of our magazine.—W. E. Musgrave, Editor.]

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—October 12, 1925—President John L. Brown presided at the meeting held at the Commercial Club, Salt Lake City, Monday, October 12, with twenty-five members and two visitors present.

Applications for membership of H. W. Sherman and Leslie B. White were read and turned over to the board of censors.

H. P. Kirtly, reporting for the building committee, stated that land has been purchased and plans are being drawn up. The financial plan has been completed.

O. C. Ewing, former member, now of California, gave an address.

Francis W. Brown was elected to membership.

October 26, 1925—This meeting was held at the Commercial Club, with President John Z. Brown in the chair, and fifty members and one visitor present.

President Brown gave a short talk on medical ethics

and commended the California law relative to expert testimony.

Leslie B. White was unanimously elected to membership.

The program was limited to talks by three of the members who had recently been abroad; the first two speakers having been on the Inter-State Post-Graduate Tour.

E. F. Root confined his remarks chiefly to surgical subjects and gave a very interesting discussion on the surgical procedures he had witnessed in Canada, British Isles, and on the continent of Europe.

W. G. Schulte discussed the social aspects of the tour, and also the genito-urinary work he had seen in the visited countries.

C. G. Albaugh talked chiefly of his observations in Vienna. In addition to interesting medical subjects, he gave a very comprehensive insight into the economic conditions existing in the various continental countries.

Fred Stauffer reported for the building committee. He announced that wrecking of the old building had started, and urged more subscriptions so as to build a ten-story building instead of one of eight. E. F. Root emphasized Stauffer's remarks and told about the beautiful new medical building in Portland, Oregon.

Fred Peterson told about the cost of maintaining the emergency hospital and the tendency of people who are able to pay a physician to take advantage of the hospital. He urged that each person treated at the hospital be made to pay for the treatment, providing their circumstances were such as to allow it. He intimated that compensation cases were being sent there for first-aid treatment. There was further discussion of the existing conditions by A. C. Callister and John Z. Brown.

President Brown referred the matter to the Public Health and Legislation Committee for investigation, and appointed Fred Peterson on the committee temporarily in the absence of Chairman Sol G. Kahn. Fred Peterson moved that the president of the society act a third member of the committee in the absence of Chairman Sol G. Kahn and, further, that the committee interview the present Mayor and commissioners, and also the candidates for commissioners, as to their views on the conduction of the emergency hospital, and also that the society be circularized by cards not later than Saturday, October 31, 1925, which would give information as to the views of the present commissioners and the candidates for that office. President Brown suggested that Fred Peterson act with the committee. The motion was seconded and carried.

The committee acted promptly and submitted their report to the members of the society in a letter, which states:

"In accordance with motion passed at our last regular meeting, your Committee on Public Health and Legislation called on the candidates who are seeking the office of City Commissioner at next Tuesday's election.

All four candidates stated that they favor the city's making a reasonable charge for professional services rendered to people who are able to pay for the same."

To which Associate Editor Giesy adds this note:

"This is a very good idea—looking to the prevention of the taking of an undue advantage, by persons able to pay, of the free clinics—a thing which recently has been subjected to far too much abuse."

November 9, 1925—The regular meeting of the Salt Lake County Medical Society was held at the Emergency Hospital, Public Safety Building, Salt Lake City, Utah, on the above date. The meeting was called to order by President John Z. Brown. Sixty members and four visitors were present.

The secretary read the resolution passed by the Carbon County Medical Society November 8, 1925. No action taken.

The scientific program was arranged by City Health Commissioner Willard Christopherson. The first paper was by W. A. Pettit of the Department of Epidemiology on what his department hopes to accomplish.

The next paper was by M. J. Connelly, who discussed the inspection of milk, meat, and food.

The activities of the Venereal Clinic were discussed by E. Spencer Wright.

Walter L. Felt gave a short talk on the Baby Clinic and its management.

Evan Gillchrest told about the laboratory work and mentioned especially the water analysis.

J. J. Galligan gave a short talk on the Emergency Hospital and its management.

The last paper was by City Health Commissioner Willard Christopherson, who discussed the organization and the cost of maintaining the City Health Department. He told in detail about chlorinization of the water, and urged the society to back the department and to allay the idea prevalent among the laity that the chlorine is injurious to the health of the people. General discussion followed by F. S. Scott, L. J. Paul, A. A. Kerr, W. F. Beer, Earl Van Cott, C. M. Benedict, C. L. Shields, and S. H. Allen. Major S. C. Gurney, United States Army, mentioned his experience with chlorinization in the Philippines, and stated that he never observed a case of diarrhea due to chlorine.

President John Z. Brown announced the appointment of W. F. Beer on the Committee on Necrology.

Fred Stauffer reported the progress for the building committee.

Willard Christopherson announced that the Emergency Hospital and City Health laboratories were open for inspection, and he passed around cigars.

Nevada State Medical Association

A. J. HOOD, M. D., Elko.....President
HORACE J. BROWN, M. D., Reno.....
.....Secretary and Associate Editor for Nevada

News Items From Nevada State Medical Association—The Nevada State Board of Medical Examiners met at Carson City, November 2 and 3, and held an examination of the following three medical doctors:

M. L. Herzig, formerly of Seattle, Washington.

E. L. Creveling, formerly of Jersey City, New Jersey.

H. C. Hill, formerly of Streator, Illinois.

The staff meeting of St. Mary's Hospital, Reno, is held on the second Monday of each month.

The Washoe County Medical Society meeting is held in the Chamber of Commerce at Reno on the second Tuesday of each month. Visiting doctors are welcome.

Charles W. Blake, formerly of Tonopah and later of New York City, is located in the Washoe County Bank Building, Reno.

M. L. Herzig is in the Baroni Building, Reno.

E. L. Creveling is located at 17 North Virginia Street, Reno.

H. C. Hill is located in the Fordonia Building, Reno.

C. E. Piersall is attending the annual conference of the secretaries of the Constituent State Medical Associations in Chicago.

Washoe County Medical Society (reported by Henry Albert, secretary) — October 13, 1925 — A. R. DaCosta moved that we adopt the American Medical Association auto emblem as our official emblem. Carried.

J. L. Robinson demonstrated an electrical appliance for applying moist or dry heat to the neck, eye, etc.; also an appliance to heat paraffin which is sprayed on burned surfaces.

C. E. Piersall read a paper on galvanic therapy.

J. E. Pickard and A. R. DaCosta discussed and told interesting experiences with the galvanic current.

The meeting adjourned.

November 12, at the Y. M. C. A. building, President Vinton A. Muller presiding.

Minutes—The minutes of the previous meeting of October 13, were read and approved.

Business—President Muller presented a request from Mrs. S. H. Wheeler, secretary of the Child Welfare Division of the State Board of Health, that she be privileged to call on members of the society to occasionally address the nurses employed by that organization. By

vote, a majority signified their willingness to address the nurses.

An application from Dr. Herzig to join this society was presented and referred to the Board of Censors.

Program—Dr. G. L. Servoss presented a paper on "Diabetes and Common Sense." He emphasized especially the importance of making a determination of the dietary requirements of the individual before giving insulin. The paper was discussed by Drs. Albert and Pickard.

Dr. A. B. De Chene gave a report of the symptoms which she personally experienced while affected by the recent epidemic ailment attributed to the water supply.

The source of the toxic material which caused the recent water-borne epidemic of enteritis was discussed by Dr. Albert.

Attendance—Members: Albert, Blake, Caples, Da Costa, De Chene, Dalby, Fuller, Lehnars, Muller, Morrison, Pickard, Piersall, Richardson, and Servoss.

M. O. R. C.

Ninth Corps Area—California, Nevada, Utah, Wyoming, Montana, Idaho, Washington, Oregon, and the territory of Alaska.

Headquarters, Ninth Corps Area, has just issued orders assigning 222 Medical Reserve Officers to medical units and appropriate duties therein. This seems like a large number of doctors, but it is only one-sixth of the medical personnel that these same units require, and only one-tenth of the medical personnel required from the Ninth Corps Area under the National Defense Act. With these assignments, some of these units are taking on the appearance of organization. The general policy, in respect to such assignments, is to give a certain policy preference to units having priority of mobilization in the general defense plan.

The Surgeon, Ninth Corps Area, informs that mobilization plans in blank, have been completed by him and are in readiness to send out to the Commanding Officers of Medical Reserve Corps units as they accomplish a satisfactory organization for administrative purposes. The Commanding Officer merely has to enter certain data in spaces left blank for the purpose, and the document becomes a complete guide to prompt mobilization.

For consideration in connection with the mobilization plan thus completed, the Surgeon, Ninth Corps Area, has also prepared, and will send out to Commanding Officers, a reminder list showing each administrative step which should be taken, in its proper sequence, during the period of mobilization.

If such guides had been available during medical mobilization during the late war, a vast amount of inefficiency and delay would have been averted. Their availability now is merely an expression of one way by which the National Defense Act is operating in the prevention of similar difficulties in any future emergency.

To facilitate the development of the Medical Reserve Corps at large, and to give general aid in respect to the organization of its hospitals and other medical units, certain Reserve Medical Officers have been designated to act as local representatives of the Surgeon, Ninth Corps Area, within their respective geographical limits. These officers are supported by committees, of which they are chairmen. One other Reserve Medical Officer and the regular army Surgeon at the adjacent military post compose the remainder of each such committee.

These committees are:

For San Francisco and Northern California—Colonel George Franklin Shiels, Medical Reserve, 68 Post street, San Francisco, chairman; Major Sam F. Parker, M. C., Fort Winfield Scott.

For Los Angeles and Southern California—Colonel Charles W. Decker, Medical Reserve, 2417 W. Twenty-third street, Los Angeles, Cal., chairman; Major Val. C. Miltenberger, M. C., Fort MacArthur.

The above named officers are prepared to assist the Medical Reserve Corps movement in every possible way. Members of the profession desiring commissions in the

Medical Reserve Corps would do well to consult them. Their advice and aid is available to officers already commissioned, in building up hospitals and other units into complete, well-rounded organizations, and in helping in every other way practicable.

Albert C. Carlton, Lieutenant-Colonel, Medical Reserve Corps, 177 Post Street, San Francisco, has just been awarded the Wellcome first prize of a gold medal and \$300 by the Association of Military Surgeons of the United States for the best essay on "The means and policies which will best enable this association to increase its membership and accomplish its patriotic objects as stated in its constitution." The competition was open to all medical officers of the Regular Army, Navy, National Guard, Organized Reserves, and Public Health Service.

The Association of Military Surgeons is an organization chartered by Act of Congress of the United States, and has now had an existence of some thirty-five years. It has a large membership in the militant medical services, and publishes a monthly journal—the "Military Surgeon"—which is a chronicle of current medico-military affairs and progress. Being of a national character, its annual meetings are habitually attended by medical officers of many foreign military and naval services, sent there as representatives of their respective governments. The winning of its annual prize brings much professional distinction to the successful essayist.

Evacuation Hospital No. 90, San Diego, Colonel Alfred E. Banks, Medical Reserve, commanding, is taking a leading position in interpreting the spirit of M. O. R. C. Service, and has now nearly completed its enrollment of officers and will shortly be placed on a mobilization basis, in readiness for emergency. Colonel Banks and the officers under him have gone ahead with the development of their unit in a very efficient way, and are now giving attention to the enrollment of their Reserve Nurse Corps personnel. Evacuation Hospital No. 90 made an excellent showing in the Preparedness Day parade. The officers of this unit now hold dinner conferences once a month for professional information, as well as for get-together purposes. At the dinner conference held on October 21, Lieutenant-Colonel Maynard C. Harding, Medical Reserve, and Major Clair L. Stealy, Medical Reserve, presented a formal plan for peacetime training within the unit. Lieutenant-Colonel C. Pennel Baxter, Medical Reserve, also delivered an address on medical administration pertaining to army hospital units. This was the first of a series of similar addresses for the benefit of the staff of Evacuation Hospital No. 90. The transactions at these meetings of the staff of Evacuation Hospital No. 90 regularly appear in the Bulletin of the San Diego County Medical Society.

The Sacramento Society for Medical Improvement, at its first meeting in September, went on record as being in favor of sponsoring the Reserve Medical Units assigned to Sacramento County. These units include Hospital Trains Nos. 44 and 71, and Medical Laboratories Nos. 1 and 4 (both aviation). It also directed its secretary to prepare a questionnaire to determine the possibility of providing the required medical personnel from within its own membership.

Colonel S. C. Baldwin, Medical Reserve, Salt Lake City, Utah, has been designated as liaison officer for Medical Reserve Corps affairs in the States of Utah and Nevada. Colonel Baldwin has been very active and successful in promoting Medical Reserve Corps affairs, and particularly in organizing General Hospital No. 61, which has the Latter Day Saints Hospital of Salt Lake City as its parent institution.

At the regular meeting of the Salt Lake County Medical Society of September 14, 1925, it was moved and carried that the society endorse the Medical Reserve units allocated to that county for home station, and that a committee be appointed to determine the best ways for the promotion of their interests. The units concerned are

General Hospital No. 61, Station Hospital No. 136, Hospital Train No. 1, and Veterinary General Hospital No. 54.

While the Reserve Corps of the Medical Department of the Ninth Corps Area is still far short of medical officers, the dental branch has not only filled all its vacancies in the Reserve Corps, but contributed a surplus of nearly 50 per cent beyond the requirements of the Ninth Corps Area plans.

The Medical Administrative and Sanitary Reserve Corps have likewise filled their quota. Most of the quartermasters and chaplains needed to further officer the Reserve Corps hospitals have already been obtained, and the few vacancies remaining will shortly be filled.

Only the medical profession has failed to measure up to its responsibilities. The personnel of Medical Reserve Officers enrolled is not half as large as it should be. Yet the whole plan of Reserve Medical Service, and the operation of its medical units, is built about the medical profession.

Why is it that the medical profession has lagged behind, when the other branches that work with it in its patriotic and humanitarian mission have gone "over the top"?

MORE NAMES TO THE HONOR ROLL

The following are the Reserve Medical Officers already appointed to command Reserve Medical units in California. There are some other medical units, for which no selection of Commanding Officers has as yet been made:

Colonel Alfred E. Banks, Med. Res., 723 Electric Building, San Diego, Evacuation Hospital No. 90.

Colonel Harry G. Ford, Med. Res., 2345 Lake Street, San Francisco, Evacuation Hospital No. 88.

Colonel Henry H. Lissner, Med. Res., c/o Union Bank and Trust Co., Los Angeles, General Hospital No. 35.

Colonel James A. Mattison, Med. Res., Soldiers' Home, Sawtelle, General Hospital No. 142.

Colonel Howard C. Naffziger, Med. Res., 2555 Larkin Street, San Francisco, General Hospital No. 30.

* Colonel John W. Shiels, Med. Res., 291 Geary Street, San Francisco Headquarters Ninth Corps Medical Service.

Lieutenant-Colonel Charles L. Garvin, Med. Res., Box 83, Livingston, Station Hospital No. 139.

Lieutenant-Colonel Morton R. Gibbons, Med. Res., 3979 Washington Street, San Francisco, General Hospital No. 138.

Lieutenant-Colonel Charles D. Lockwood, Med. Res., 295 Markham Place, Pasadena, Surgical Hospital No. 71.

Lieutenant-Colonel Levi L. Riggins, Med. Res., 205 Dodworth Building, Pasadena, Surgical Hospital No. 72.

Lieutenant-Colonel Fred C. Shurtleff, Med. Res., 709 Brockman Building, Los Angeles, Station Hospital No. 150.

Lieutenant-Colonel Charles T. Sturgeon, Med. Res., 1136 West Sixth Street, Los Angeles, Evacuation Hospital No. 81.

Lieutenant-Colonel Neal N. Wood, Med. Res., 1100 Mission Road, Los Angeles, Station Hospital No. 144.

Major Walter A. Bayley, Med. Res., 1216 West Forty-eighth Street, Los Angeles, Surgical Hospital No. 67.

Major Arthur N. Bobbitt, Med. Res., 411 Citizens Savings Bank Building, Pasadena, Medical Laboratory No. 11.

Major Peter De Obarrio, Med. Res., 1217 Sherman Street, Alameda, Medical Laboratory No. 1.

Major Joseph F. Grant, Med. Res., 4483 Hermosa Way, San Diego, Medical Laboratory No. 5.

Major David H. Keller, Med. Res., Old Colony Club, Los Angeles, Hospital Train No. 55.

Major Joseph G. Noble, Med. Res., U. S. V. Hospital No. 64, Camp Kearney, Hospital Train No. 71.

Major John H. Woolsey, Med. Res., University of California Hospital, San Francisco, Surgical Hospital No. 65.

* Assigned as Corps Surgeon. (No C. O. authorized.)

Assignments and Changes in Personnel—California, Utah and Nevada

Presidio of San Francisco, Cal., October 20, 1925.

The following-named Reserve Officers are assigned to the unit as indicated below, and to the positions as indicated after their respective names:

General Hospital No. 140, Zone of Interior:

Lieutenant-Colonel John M. Lacey, Med. Res., 1052 West Sixth Street, Los Angeles, Calif., as Commanding Officer.

Lieutenant-Colonel Walter F. Wessels, Med. Res., 254 South Gramercy Place, Los Angeles, Calif., as Chief of Medical Service.

First Lieutenant Clayton R. Johnson, Med. Res., 2409 South Bronson Avenue, Los Angeles, Calif., as Roentgenologist.

Captain Harry E. Straub, Dent. Res., 1743 Micheltorena Street, Los Angeles, Calif., as Dental Surgeon.

Eighty-first Evacuation Hospital, Third Army:

First Lieutenant Walter E. MacPherson, Med. Res., 1100 Mission Road, Los Angeles, Calif. (temporary address, 946 E Street, Sparks Nev.), as Surgical Ward Officer.

First Lieutenant David A. Schmid, Med. Res., 1008 Por-

ter avenue, San Fernando, California, as Surgical Ward Officer.

Sixty-seventh Surgical Hospital, Third Army:

First Lieutenant Clarence W. Giegerich, Mar. Res., 627 Acacia Street, Glendale, Calif., as Registrar, C. O. Detachment of Patients.

Eighty-eighth Evacuation Hospital, Sixth Army:

The following-named Reserve Officers are assigned, as indicated:

Major Raymond A. Babcock, Med. Res., Main and Commercial Streets, Willits, Calif., as Assistant to Chief of Medical Service.

Major Francis S. Cook, Med. Res., Brentwood, Contra Costa County, Calif., as Assistant to Chief of Medical Service.

Major William J. Hosford, Med. Res., 57 Nevada Street, Santa Cruz, Calif., as Assistant to Chief of Surgical Service.

Major Irving W. Higgins, Med. Res., Live Oak, Calif., as Roentgenologist.

First Lieutenant Elmer F. Prescott, Mar. Res., 676 Mission Street, San Francisco, Calif., as Adjutant and Assistant Fire Marshal.

Major Orrin S. Cook, 749 Twentieth Avenue, San Francisco, Calif., as Roentgenologist.

First Lieutenant James P. Warren, Mt. Zion Hospital, San Francisco, Calif., as Medical Ward Officer.

First Lieutenant Otto L. Schattenburg, Mt. Zion Hospital, San Francisco, Calif., as Medical Ward Officer.

Major Clark L. Abbott, Med. Res., 126 Santa Fe Avenue, Point Richmond, Calif., as Assistant to Chief of Surgical Service.

First Lieutenant Harold L. Fraser, Med. Res., 939 Adeline Street, Oakland, Calif., as Medical Ward Officer.

First Lieutenant Henry P. Buckingham, Med. Res., 3902 California Street, San Francisco, Calif., as Surgical Ward Officer.

First Lieutenant Jack L. Stein, Med. Res., 2210 Los Angeles Avenue, Berkeley, Calif., as Medical Ward Officer.

First Lieutenant Carlyle M. Pearce, Med. Res., 2307 Bartlett Street, Oakland, Calif., as Medical Ward Officer.

First Lieutenant Frank K. Haight, Med. Res., 1283 Second Avenue, San Francisco, Calif., as Surgical Ward Officer.

Major Arthur E. Irving, Dent. Res., Box 22, Kelseyville, Calif., as Dental Surgeon.

First Lieutenant Ernest R. Ker, Dent. Res., 354-356 Flood Building, San Francisco, Calif., as Dental Surgeon.

First Lieutenant Tiberius B. Molsbergen, Mar. Res., 900 Sierra Street, Reno, Nev., as Registrar and C. O. Detachment of Patients.

Second Lieutenant Harry L. Bradley, Mar. Res., 1014 Clay Street, Oakland, Calif., as Detachment Commander.

The following-named Reserve Officers are relieved from their present assignment and are assigned as indicated:

Colonel Frank C. Wiser, Med. Res., 161 South Normandie Avenue, Los Angeles, Calif., from assignment to the 349th Medical Regiment, Nineteenth Corps, and assigned to General Hospital No. 144, Zone of Interior, as Commanding Officer.

Lieutenant-Colonel Fred C. Shurtleff, Med. Res., 709 Brockman Building, Los Angeles, Calif., is relieved from assignment to Station Hospital No. 150, Communications Zone.

The following-named Infantry Reserve Officers are relieved from assignment to Corps Headquarters Company, Nineteenth Corps:

Captain John L. Cogan, El Centro Apartments, Alameda, Calif.

First Lieutenant Chester A. Fee, P. O. Box 2785, Taft, Calif.

First Lieutenant Edward C. Schumacher, Ross Fire Department, Ross, Calif.

The following-named Infantry Reserve Officers are assigned to Corps Headquarters Company, Nineteenth Corps:

Captain Tom Barker, 1216 Mission Street, San Francisco, Calif.

First Lieutenant Harry Brown, 1709 Hayes Street, San Francisco, Calif.

First Lieutenant Joseph S. Flynn, 5026 Geary Street, San Francisco, Calif.

Second Lieutenant Robert M. Apple, 648 Waller Street, San Francisco, Calif.

Lieutenant-Colonel Neal N. Wood, Med. Res., 100 Mission Road, Los Angeles, Calif., is relieved from assignment to Station Hospital No. 144, Communications Zone.

The following-named Medical Corps Reserve Officers are assigned to units as indicated:

Major Ernest W. Cleary, 146 Chapin Lane, Burlingame, Calif., to Eighty-eighth Evacuation Hospital, Sixth Army, as Assistant to Chief of Surgical Service.

Captain William F. McCool, 1026 Marsh-Strong Building, Los Angeles, Calif., to Ninetieth Evacuation Hospital, Sixth Army, as Evacuation Officer.

Captain Irvin H. Betts, 411 West Grove Street, Visalia, Calif., to Sixty-fifth Surgical Hospital, Third Army, as Assistant Operating Surgeon.

First Lieutenant John Ohanneson, Mt. Zion Hospital, San Francisco, Calif., to Eighty-eighth Evacuation Hospital, Sixth Army, as Surgical Ward Officer.

First Lieutenant Lewis A. Alesen, 1675 West Santa Barbara Avenue, Los Angeles, Calif., to Eighty-first Evacuation Hospital, Third Army, as Medical Ward Officer.

The following-named Reserve Officers are assigned to the unit as indicated, and to the positions as indicated after their respective names:

General Hospital No. 46, Communications Zone:

Major Rossner E. Graham, Med. Res., 230 Grand ave., Oakland, Calif., as Assistant to Chief of Medical Service.

General Hospital No. 47, Communications Zone:

Lieutenant-Colonel Howard W. Seager, Med. Res., 749 South Berendo Street, Los Angeles, Calif., as Chief of Medical Service.

Major Joseph A. Parks, Med. Res., Lee Avenue, La Mesa, Calif., as Assistant to Chief of Medical Service.

Major Lambert B. Coblenz, Med. Res., 205 West Chapel, Santa Maria, Calif., as Assistant to Chief of Surgical Service.

Major Thomas C. Myers, Med. Res., 1501 South Figueroa Street, Los Angeles, Calif., as Assistant to Chief of Surgical Service.

General Hospital No. 138, Zone of Interior:

Major Sydney V. West, Med. Res., 304 Broadway, Chico, Calif., as Assistant to Chief of Surgical Service.

First Lieutenant Morrell E. Vecki, Med. Res., University of California Hospital, San Francisco, Calif., as Surgical Ward Officer.

First Lieutenant Percy B. Gallegos, Med. Res., Lane Hospital, San Francisco, California, as Surgical Ward Officer.

NEWS ITEMS FROM THE CALIFORNIA BOARD OF MEDICAL EXAMINERS

C. B. PINKHAM, M. D., *Secretary*

A new method for treatment of paralysis was disclosed in the recent arrest of Jean Campbell, San Diego, California, who is reported to have mulcted a hopelessly paralyzed patient out of \$108 under the theory that, by tickling the patient's nostrils with odd pieces of paper, the patient would be caused to sneeze and thereby relieve the pressure on the brain that caused the paralysis.

A flight into high finance was disclosed in the arrest of E. A. Mitchell, an interior decorator, charged in Los Angeles with violation of the Medical Practice Act. He is alleged to have made physicians and sold them "territory" wherein to work. Another venture was selling certificates for life-time service in the Los Angeles County Hospital. Mitchell is reported to have received \$200 cash in advance for treating an 11-year-old diabetic patient whose trouble he diagnosed as dropsy of the lungs. Following his conviction he was sentenced to ninety days in the county jail.

Since filing of a complaint, the Bakersfield police are reported looking for "Dr." Harley Hulse Heddens on on a charge of violation of the Medical Practice Act. His philosophy is expressed on the front page of his record book. "On the plains of hesitation bleach the bones of countless millions who at the time of victory sat down to wait and, waiting, died." Not so with Heddens, who did not "tarry long on the plains of hesitation. The minute he found the police didn't have a good tight grip on him he was off." According to reports, he collected \$1688.55 in the period between June 7 and December 31, 1924, and \$507.25 from January 1, 1925, to April 18, 1925, in his illegal practice of medicine. Many ergot prescriptions were reported given his women patients, and many are reported to have paid either \$35 or \$50 for an operation. No one by the name of H. H. Heddens can be found as licensed to practice medicine in any state or territory of the United States, nor can a record of him be found with the Board of Osteopathic Examiners or the Board of Chiropractic Examiners. P. F. Collier & Son report the delivery to Heddens of a set of "Harvard Classics," representing \$110, for which they have not been paid in full.

Behind the cloak of the Chirothesian Church of Faith are hiding many of those engaged in violation of the Medical Practice Act, some of the more recent ones being M. T. Larkin, Los Angeles; Josephine M. Fernald, Los Angeles; and Allen Mills, Richfield, Tehama County, California. The proponents of this organization have declared that they will make the ordination certificate of the Chirothesian Church of Faith equally recognized with a medical diploma. The recent conviction of Chirothesian Allen Mills for violation of the Medical law has been upheld by the Appellate Court.

Jacob Nilmeier, terming himself "bone specialist," again charged with violation of the Medical Practice Act in Fresno on April 29, 1925, has not as yet been given preliminary hearing.

Just why the authorities of Monterey County seem loath to bring to trial in the Superior Court "Dr." Christopher (Charles) Liscum, held for trial by the Justice Court at Castroville early this year, is a matter of no little importance. Liscum came to California after Oregon newspapers had related his arrest on a bootlegging

charge, his asserted conviction of driving an auto while intoxicated; and a term in the federal penitentiary on McNeil's Island, following his conviction of violation of the Harrison narcotic law. While here he is reported to have been placed under supervision of the probation officer for failure to provide for a minor child. *What's the matter in Monterey County?*

Following the filing of a complaint by the energetic law enforcement officials of Modesto, charging N. S. Sue, Chinese herbalist, of violation of the Medical Practice Act, the defendant recently pleaded guilty and paid a fine of \$400.

Nelford B. Hollingsworth, a professed divine healer, recently pleaded guilty in Los Angeles of violation of the Medical Practice Act. He evidently could not pray hard enough, as in addition to prayer he used massage, alcohol rubs, and fig pills.

Susan E. Davis, alleged to have been carrying on rather an extensive practice, pleaded guilty in Bakersfield to a violation of the Medical Act and paid a fine of \$100.

J. Lafayette Berry, who, according to the records formerly conducted a traveling tent show under the name of "Bloodless Berry," and the revocation of whose license October 21, 1919, has been sustained by the California courts, was recently charged in Los Angeles County with violation of the Medical Practice Act in connection with the treatment of one suffering from cancer of the face, the report stating "there is now a hole in the patient's cheek which apparently cannot be healed."

James R. Dow, whose medical training, according to his reported admission, consisted in acting as a "bell boy," and later a nurse at Bellevue Hospital, New York, recently pleaded guilty in Los Angeles on a charge of violation of the Medical Practice Act and was given a ninety-day jail sentence, suspended for a period of two years on condition that he refrain from further violation.

A recent report from Ventura County that the body of an infant, dying shortly after birth attended by an unlicensed midwife, the poor little body crushed down into a macaroni box for a coffin, neither birth nor the burial having been reported to the authorities, makes us realize our problem in handling maternity work among our foreign population.

William A. Strole, M. D., of Los Angeles recently pleaded guilty to a violation of the Harrison Narcotic Act in the United States Court, Southern District, and paid a fine of \$500.

Recent press dispatches relate that the State Board of Chiropractic Examiners is engaged in investigation of alleged trafficking in chiropractic diplomas by certain California institutions.

Percy Purviance, proprietor of the Berkeley Chiropractic High School and the Berkeley College of Chiropractic, according to reports has been cited to appear before the Chiropractic Board on November 5, 1925, to show cause why his license, alleged to have been obtained through "fraud and deception," should not be revoked.

The Sacramento Bee of September 17, 1925, relates T. Wah Hing, Chinese herbalist, has been indicted by the Grand Jury, it being charged "that Hing has treated various patients, acting in the guise of a physician, without being the possessor of a diploma from an accredited medical college, and without having passed the examination prescribed by law." Hing has conducted an office in Sacramento for many years, and on more than one occasion has been charged with violation of the Medical Practice Act, as well as the state poison law, in connection with narcotics.

L. T. A. Hotten, also known as Hottendorf, was recently charged in Los Angeles with selling narcotics to patients, according to Los Angeles papers.

Dio Lewis, reported to have wandered about the parks of Los Angeles operating on corns—sharpening his instruments on his shoe—was recently sentenced to 180 days in jail by Police Judge Richardson in Los Angeles for violation of the Medical Practice Act. An infection following Lewis' operating is said to have caused one of his "patients" considerable trouble.

According to the Los Angeles Examiner of September 5, 1925, J. J. Hansen, licensed chiropractor, was held on a charge of performing operations, for which he was unqualified. Following his plea of guilty, he was sen-

tenced to pay a fine of \$100 or serve 100 days in the county jail.

Christine Stewart Loose, Oakland, was recently charged with murder in connection with the death of Charlotte Sweet, following an alleged criminal abortion. She is referred to as a retired physician and surgeon, but no record of her medical credentials has been found.

James A. McLean, native of Martinique, self-asserted geologist, evolutionist, pathologist, psychologist, anatomist, biologist, chemist, etc., was recently charged in San Francisco with violation of the Medical Practice Act. According to newspaper reports he claims to be able to turn the sun's rays directly into alcoholic beverages.

Arthur E. Pike, D. O., Mayor of Signal Hill, Long Beach, California, was reported recently charged with violation of the Medical Practice Act by the investigator for the Board of Osteopathic Examiners.

M. A. Crespo, self-styled medical man and occult Messiah, forfeited \$1000 bail, following the Los Angeles Superior Court's affirmation of his sentence to pay a fine of \$200 and serve 120 days in the county jail on a charge of violation of the Medical Practice Act.

CORRESPONDENCE

To the Editor:

IN CALIFORNIA AND WESTERN MEDICINE for November, 1925, on page 1465, we notice an announcement of the Colloquia at the San Francisco Hospital. May we call your attention to the fact that the Surgical Colloquium is held on Thursday instead of Tuesday, as stated in this account, and the Medical Colloquium is held on Friday.

W. OPHULS, *Dean*.

[In correcting the error we wish to repeat that brief extracts of the discussions at these colloquia make profitable reading for doctors everywhere.—EDITOR.]

To the Editor:

Is Christian Science harmless? Let us see! A few days ago one of our architects came into my office. His eye fell upon a pamphlet lying on my desk, on the cover of which was printed in large type the word "diabetes." He said, "That makes me sad." I said, "Why?" He said: "I had an excellent office assistant—a very bright and capable young woman, a graduate of the University of California; she developed diabetes. I pleaded with her to avail herself of the benefits of modern medicine, including insulin. She went to Christian Science. I continued to plead with her. She told me to cease, as it was interfering with her 'treatment.' I desisted. Her practitioner told her to pay no attention to diet; eat anything she wanted; only keep her mind fixed on the teachings of Christian Science." "One Saturday afternoon," he continued, "I helped her to the ferry. Two days later she died." To tell a diabetic to disregard diet is like pouring coal oil on a fire.

Another case, somewhat less well authenticated, however: One of our prominent businessmen contracted pneumonia. Again Christian Science was invoked. Later, when the footsteps of approaching death became audible to the dull ear of the practitioner, the unfortunate patient was hurried away to a hospital to die and to have his death certificate signed by a physician.

No physician should ever sign a death certificate under such circumstances. The case should be sent to the coroner, so that his verdict may place the responsibility where it belongs. We should set our faces hard against this thing. No sooner is the victim of their criminality safely buried by the courtesy of our profession, than they turn upon us and assert that it was a medical death; they had nothing to do with it.

Such incidents as I have related above are going on all about us. The extent of it we are unable to comprehend.

They are becoming sufficiently powerful to intimidate the public press. With the press paralyzed they may attempt to lay their hands upon our government. They now aspire to control legislation. Once armed with the full power of the state, it would be difficult to overestimate the harm they would do the world.—J. A. S., M. D.

NEXT YEAR, IN CALIFORNIA AND WESTERN MEDICINE

CALIFORNIA AND WESTERN MEDICINE has accepted for publication in forthcoming numbers the following essays, which will be published during the coming year as suitable space is available:

- Samuel Ayres, Jr.
Present Status of Bismuth in Anti-Syphilitic Treatment.
- William H. Barnes.
Virulent Surgical Infections.
- Dean Blake.
Some of the Functions of Humidity.
- W. W. Boardman.
Cholecystography—Its Value as a Diagnostic Procedure.
- Emil Bogen.
Recent Studies in Scarlet Fever.
- Andrew Bonthius.
Clinical Aspects of Intestinal Protozoiasis.
- LeRoy Brooks.
A New Technique of Unmodified Blood Transfusion.
- Ernest M. Burns.
Vincent's Infection—Its Significance as a Precursor of Pyorrhoëa and Possibilities as Cause of Other Diseases.
- H. E. Butka.
Infectious Mononucleosis, With Report of Five Cases.
- Edmund Butler and G. D. Delprat.
Intestinal Obstruction.
- Lenore D. Campbell.
Giant Cell Tumors not Connected to Bones.
- Burns Chaffee.
Progress of Treatment for Hypertrophic Stenosis of the Pylorus.
- Thomas J. Clark and Frank H. Stibbens.
Skin Diseases in Twins.
- Fred B. Clarke.
Lupus Erythematosus Acutus Disseminatus.
- Harry Theodore Cooke.
Antagonistic Functions of the Uterus in Relation to Regional Nerve Blocking.
- E. F. F. Copp.
Effects of Insulin Treatment on Experimental Diabetes of Dogs.
- Michael Creamer.
Menorrhagia of Unusual Etiology.
- Wilson T. Davidson.
Diagnosis of Chronic Amebiasis.
- Paul J. De River.
Present-Day Advance in Plastic Surgery, With Reference to Correction of Deformities of Nose.
- Henry Dietrich and Hugh K. Berkley.
Mongolian Idiocy.
- Arthur N. Donaldson.
Relation of Protein Foods to Hypertension.
- John B. Doyle.
The Recognition of Psychoneuroses.
- D. M. Ervin.
Edema With the Use of Insulin.
- Newton Evans and Philip J. Tunnell.
Differential Leucocyte Count in Acute Inflammatory Conditions of Surgical Importance.
- Fred R. Fairchild.
Surgical Judgment.
- Franklin Farman.
Operative Treatment of Rupture of the Male Urethra.
- Paul A. Ferrier.
Urethral Caruncle.
- Kendal P. Frost.
Syphilis in Pregnancy.
- Kendal P. Frost and George F. Koetter.
Favus.
- Mrs. Mabel F. Gifford.
Speech Defects and Disorders.
- Arthur Stanley Granger.
Clinical Significance of Bundle Lesions.
- Ben E. Grant.
Report on Fifty Cases of Diabetes Treated With Insulin.
- Lawrence K. Gundrum.
Nasal Ganglion Neuroses.
- P. J. Hanzlik.
Peripheral Nerve Mechanisms in Chemosis and Some Other Edemas.
- Frank Hinman.
Renal Counterbalance.
- Frank Hinman.
Treatment of Enlargement of the Prostate, and Results Obtained by Modification of Young's Perineal Prostatectomy.

Index—California and Western Medicine

Volume XXIII, 1925

In preparing the index to this volume, we have followed the method of an alphabetical subject and author index combined. It is not as full perhaps as it should be, because it would take most of the time of an indexing secretary to prepare as complete an index as we would like to see. However, it is full enough so that any major subject discussed during the year and the names of all authors may be readily located.

An ever-enlarging circle of physicians who read systematically are finding the Cumulative Index published quarterly by the A. M. A., and sold for a nominal subscription, of incalculable value. Everything published in CALIFORNIA AND WESTERN MEDICINE, as well as all other worthwhile medical magazines, is completely indexed in the "Cumulative" in a most complete author and subject index. Our editorial staff use this volume constantly.—EDITOR.

A

- ABDOMINAL surgical conditions, acute, importance of prognosis in (R. E. Skeel), 1144.
- ABLAHADIAN, E. and HALL, H. A.—The function of the spleen, 289.
- ABNORMALITIES of fifth lumbar vertebra, operative treatment of (Alfred Edward Gallant and Walter C. S. Koebig), 1162.
- ACNE VULGARIS, treatment of (Ernest K. Stratton), 1301.
- ADENOMA of thyroid (Vinton A. Muller), 176.
- AFFECTIVITY, its importance in practical medicine (C. L. Allen), 1571.
- ALDERSON, HARRY E.—Treatment of poison oak dermatitis, 982.
- ALDERSON, HARRY E. and RAWLINS, AUBREY G.—Rice-workers' dermatitis, 42.
- ALLEN, C. L.—Affectivity, its importance in practical medicine, 1571.
- ALLEN, FREDERICK M.—Remarks on the practical treatment of diabetes, 1265.
- ALLERGIC DERMATITIS (Clinical Notes and Case Reports, A. H. Rowe), 1589.
- ALLERGY and its relation to the otolaryngologist (George Pinness), 1014.
- ALLISON, C. C. (Toronto)—Clinical notes and case reports—fecal vomiting of rare origin, 1030.
- ALVAREZ, WALTER C.—Some correspondence relating to the introduction of vaccination into America, 582.
- AMEBIASIS, surgical (P. K. Gilman), 309.
- ANAPHYLACTOID REACTIONS, blood and tissue changes in (P. J. Hanzlik), 161.
- ANEMIA, splenic (Banti's disease)—pre-operative preparation and surgical treatment of (Leo Pecci Bell), 1288.
- ANESTHESIA, spinal in urology (J. C. Negley), 452.
- AREA CHANGES in hearts, showing decompensation and lowered cardiac reserve (Donald J. Frick, Robert H. Kennicott, Rolla G. Karshner), 183.
- ARTERIOSCLEROSIS, discussion of etiology, symptoms and prognosis of (John Phillips), 1121.
- ARTHRITIS, chronic, treatment of (Leonard W. Ely), 1157.
- ARTIFICIAL FEEDING of newly born infants (William M. Happ), 988.
- AS THE LAYMEN SEES US—Cultural education in medicine, specialism, and the distribution of physicians (Edward N. Ewer), 838.
- ATRESIA, congenital nasal (Francis L. Rogers), 443.
- AYRES, Jr., S.—Glucose intolerance associated with eczema, 1560.

DOCTOR:

When calling for the active principle of the Posterior portion of the Pituitary substance in solution, remember to specify PITUITARY LIQUID, ARMOUR, because it is made from U. S. government inspected glands and complies with all the requirements of the new U. S. P. X.

There are many Pituitary extracts on the market of varying strength and in order to be sure of your product, we suggest the advisability of insisting on a dependable make and commend to you ARMOUR'S because of the opportunity which our facilities make possible in the selection of raw material.

The same is true of our entire line of glandular preparations. Every particle of raw material put into process is normal in every respect and when insisting upon ARMOUR'S you may be sure of full therapeutic activity.

ARMOUR AND COMPANY

CHICAGO

The Nutritive Properties of Natural Cow's Milk are retained in **KLIM**

Analysis of
KLIM
POWDERED WHOLE MILK

	<i>Dry</i>	<i>Liquid *</i>
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	5.46%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water
KLIM is completely soluble in water of any temperature

When Used in Infant Feeding
Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

MILK atomized into filtered air sufficiently warm to cause instantaneous evaporation of the water—is KLIM.

The rapid evaporation of the water so cools the milk particles as to prevent over-heating—evidenced by the fact that in KLIM

The albumin is not coagulated

The lactose is not caramelized

The vitaminic potency is not diminished (see Dutcher and Cavanaugh--June, 1923, ed. American Journal Diseases of Children).

The enzymic reactions are normal

The powder is completely soluble

Given, also, simplicity of preparation, absolute safety and superior digestibility, the physician has at his command a worthy substitute when breast milk is insufficient

*Literature and samples
sent promptly upon request*

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

Wellsworth Refracting Outfit *for Oculists*

Here is the only complete refracting unit which is attached to the chair. It combines economy of space with convenience for the refractionist and comfort for the patient. It requires less space to house and operate than any other unit. The adjustable back, seat, headrest and arms give the patient utmost comfort.

The instrument support permits the use of each instrument independently. Each instrument swings before the patient in regular routine.

Equipped with scientifically precise Wells-worth-DeZeng diagnostic instruments, it is the most accurate and practical unit obtainable. The scientific appearance is in keeping with the dignity of the profession.

The Aim of Milk Modification

*is nicely summed up by
Kerley in his "Practice of
Pediatrics" as follows:*

“THE first aim in modification is to make the chief nutritional elements in the food prepared from cow's milk correspond grossly to the nutritional elements in human milk. The protein must be reduced, the sugar increased, and the fat reduced even slightly below that usually found in mother's milk, as the child's digestive capacity for cow's milk fat is less by from 15 to 25% than it is for human milk fat.”

When the pediatrician prescribes “Lactogen” in cases where breast milk must be supplemented or replaced, all of the above important modifications of cow's milk have been done in a most exacting, scientific manner in the process of manufacture of “Lactogen,” thereby offering to the pediatrician a nutriment which very closely approximates human milk in analysis and ease of digestion.

The coupon below is for your convenience and will bring you sufficient supply for a clinical trial.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

Pseudo-Appendicitis. A study of mechanical syndromes of the right lower quadrant simulating appendicitis. By Thierry De Martel and Edouard Antoine. 211 pp. Illustrated. Review copy by courtesy of F. A. Davis Company. For sale by advertisers in California and Western Medicine.

That there is need for such a book as this, is evident from the many recent articles dealing with a so-called chronic appendicitis and the poor results of insufficient surgical treatment.

The authors stress the importance of caution in dealing with patients complaining of chronic discomfort on the right side of the abdomen associated with gastro-intestinal disturbances and tenderness. Too often is such a combination of signs and symptoms hastily diagnosed as appendicitis, the appendix removed, but the patient not benefited.

Recurring symptoms referable to pathological conditions in the right flank and iliac fossa—the cecum and proximal colon—should warn against superficial methods of study. It is only by making use of all diagnostic measures available, including the "co-operation of a good internist, a good radiologist and a good surgeon," that the true condition will be determined and the proper treatment realized.

The subject is well treated in this book. The nature of pathologic changes in and about the cecum and ascending colon is presented in the introduction. These changes are studied and their effects developed clearly in the several chapters of the book.

The writers emphasize especially the importance of complete radiologic study of the entire gastro-intestinal tract, not, however, to the exclusion of data derived by any or all other means of diagnosis. The underlying cause in all cases cited in the book is a mechanical one resulting in greater or less interference with the normal march of the content of the cecum and adjoining colon.

The book is interestingly written. The authors have a message and make their points clear. Not only surgeons, but internists as well will benefit by its study.

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in —

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water. ASK YOUR PHYSICIAN ABOUT IT.

BOOK REVIEWS

(Continued from Page 1632)

Some Fundamental Considerations in the Treatment of Empyema Thoracis. By Evarts A. Graham. Review copy by courtesy of C. V. Mosby Company. For sale by advertisers in California and Western Medicine. Price, \$2.50.

This book will interest surgeons occupying themselves with diseases of the chest. It gives experiments on the pneumothorax and formulates a scientific theory for the dangers of early operations in post-pneumonic empyema.

The reviewer's practice has been to defer operation whenever dyspnea and cyanosis seem greater than might be accounted for by the rise of the exudate; he has assumed that the excessive dyspnea and cyanosis were caused by the underlying pneumonia, and has waited. Graham's book gives experiments and a scientific explanation for the clinical formula expressed above.

Clinical Therapeutics. By Alfred Martinet. Two volumes. Review copy by courtesy of the publishers, F. A. Davis Company. For sale by advertisers in California and Western Medicine.

Particularly interesting is the first volume of this work bearing on therapeutic agents and procedures. It is quite comprehensive and most descriptive. Accounts of procedures are here from the simplest and oldest, such as the seton, to artificial pneumothorax and the use of Bayeux' oxygenator.

The second volume on the treatment of symptoms and diseases is less attractive, containing little that cannot be found in innumerable sources. Nevertheless, all is in brief enough form and still comprehensive. The style is satisfactory and the print excellent. Our reviewer finds it difficult to acquire knowledge by examination of tables such as abound here.

Methods in Surgery, used in the surgical divisions of Barnes Hospital, St. Louis Children's Hospital, and Washington University Dispensary. By Glover H. Copher. Review copy by courtesy of C. V. Mosby Company. For sale by advertisers in California and Western Medicine. Price, \$3.

A manual for the surgical house officers and interns at Washington University. It gives a good idea of the exemplary organization with which Dr. Evarts Graham manages his services.

Medical Follies. By Morris Fishbein, M. D., Editor of the Journal of the American Medical Association. Review copy by courtesy of the publishers, Boni & Liveright. For sale by advertisers in California and Western Medicine.

In reviewing this well-written book we cannot do better than to quote, with our endorsement, from its review by that interesting and worthwhile weekly newspaper

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food
Skimmed Milk (1% fat)
Water

8 level tablespoonfuls
9 fluidounces
15 fluidounces

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSÉ, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue
San Francisco, Calif.

General hospital of 225 beds, accepting all cases except mental diseases. Built upon the pavilion plan, allowing large air space for each patient. The buildings occupy a full city block, built around a beautiful central court. Aseptic, operating and delivery rooms. Complete X-Ray Department with portable apparatus. Eye and Ear, Genito-Urinary Clinics. Modern Hydrotherapeutic Department, etc.

Accredited for Intern training by the American Medical Association.

Alkaline Therapy

IN DISEASED conditions foods (Fats, Carbohydrates, Proteins, Salts and Water) may be oxidized more rapidly than normal.

BECAUSE THE body stores fats, food may be withheld several days with no ill effect.

WHEN NORMAL ALKALIES are withheld, or used faster than supplied, symptoms of ACIDOSIS develop immediately.

NOT A SINGLE cell in the human body can functionate normally if the ACID-ALKALINE

equilibrium has been disturbed.

THERE IS NO therapy or treatment that will restore the patient to health until the normal ALKALINITY has been established.

TO RESTORE the NORMAL ALKALINITY it is necessary to supply the body with a carbonated alkaline drinking water containing the body SALTS AND ALKALIES in the exact proportion for assimilation.

CALSO WATER contains all the body SALTS AND ALKALIES. It is an efficient and economical method for combating ACIDOSIS. One quart daily is sufficient for ordinary cases of acidosis. Severe cases may require two or more quarts daily.

CALSO WATER is indicated in the acidosis of: Diabetes; nephritis; toxæmias of pregnancy; cyclic vomiting of children; infections; cystitis; urethritis; headaches of high blood pressure; gastric hyperacidity. In the preparation and post-operative treatment of surgical patients.

Calcium Deficiency

NOT ALONE for the creosote content may CALCREOSE be administered but also for its calcium content. Many physicians are prescribing calcium to overcome a calcium deficiency.

CALCREOSE is a mixture of approximately equal parts of creosote and calcium oxid that can be taken for a long time, and in comparatively large doses without apparently causing any gastro-intestinal disturbance; nor do patients object to its long continued use.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

A Comparison of Dried, Evaporated, and Fresh Cow's Milk—In this experiment rats were fed on a diet of white bread (crumb only) mixed with (1) fresh cow's milk, (2) dried milk, or (3) evaporated, non-sweetened milk. Throughout the study it was found that the rats fed on evaporated milk were in poorer condition than those fed on either fresh cow's milk or dried milk. It was obvious that dried milk and evaporated milk possess quite different dietetic values, and that dried milk approximates more closely to fresh cow's milk. Experiments previously reported prove that the content of vitamin B is greater in dried milk than in evaporated milk. The dried milk used was apparently quite equal in dietetic value to fresh cow's milk; if there was any advantage it was in favor of the dried milk. The evaporated milk used, however, compared less favorably with fresh cow's milk.—Gladys Annie Hartwell (British Medical Journal, June 13, 1925).

The Pathology of Peptic Ulcer of the Stomach—Howard T. Karsner, Cleveland (Journal A. M. A.), reviews extensively the literature and concludes that, pathologically, peptic ulcer is an inflammatory—perhaps primary—lesion so situated that gastric juice probably emphasizes the destruction of tissue. Various predisposing causes seem to be operative in the patients, but these are not conclusively established. The direct exciting cause of the ulcer has not yet been disclosed in such a fashion as to be beyond doubt. The persistence or chronicity of the ulcer depends on a variety of factors, none of which can be said to operate in all cases. Probably several of these factors are coincidentally in evidence. Thus, there must be considered especially hyperacidity, stasis of neuro-muscular or obstructive origin, the irritative and traumatic influence of gastric contents, and the traction of muscle about the ulcer.

BOOK REVIEWS

(Continued from Page 1636)

"Time," edited and published by laymen. The book review editor of this magazine says in part:

"Few laymen read medical journals, for they inevitably suspect, behind the lurch and trundle of ill-teamed words, the machinations of a cloudy mind." Dr. Fishbein's words are graphic; he is possessed of what George Meredith called "the first condition of sanity"—a belief that our present civilization is founded on common sense. In a new book he shows what a neat and glittering weapon this common sense may be. With it he clips down major medical follies—osteopathy, chiropractic—and passes on to offer information on various other topics.

Objective Psychopathology. By C. V. Hamilton, M. D., Director of Psychological Research, Bureau of Social Hygiene, Inc. Review copy by courtesy of the publishers, C. V. Mosby Co., St. Louis. For sale by advertisers in this issue.

A careful reading of this book confirms Hamilton's intellectual honesty and scholarly attainments. The book will be appealing to intelligent people generally no doubt, but being tinctured with reminiscences of Psychopathia Sexualis, the expediency of its circulation, as recommended among social workers and other laymen is doubtful, although the prurient-minded may find an outlet for their tendencies at any news-stand. Hamilton is to be complimented upon his successful attempt to avoid confusing nomenclature and terms which are often piled one upon another in psychological studies, and also upon his new idea of dealing with the reactive tendencies of the organism as physical, objectively measured things. Hamilton's book will be of great value to the physician and surgeon who already possesses his insight into such matters and who may not be as ignorant of them as those mentioned by Professor Robert Yerkes in the foreword of the book.

Personal Hygiene Applied. By Jesse Feiring Williams. Review copy courtesy of W. B. Saunders Co. For sale by advertisers in California and Western Medicine.

To the teachers of personal hygiene this book needs no introduction as a leading reference on its subject. To students and individuals desiring accurate, concise and usable knowledge on health matters, it can be recommended as excellent. Every chapter seems essential, and the author has made a scientific subject attractively readable.

Diseases of the Ear, Nose, and Throat. By Harold Hays. Review copy courtesy of the F. A. Davis Co. For sale by advertisers in California and Western Medicine.

Hays' new book brings our present ear, nose, and throat information up to date, and puts it in practical, usable

One of Ohio's most representative hospitals—
The Flower Hospital, Toledo, Ohio.

Making a *long story longer*

The Flower Hospital, Toledo, is added to the list of Hospitals with "American" laundries

WITH hundreds of representative American hospitals and institutions already operating their own laundries with "American" equipment,

the list still grows steadily every month. Now the Flower Hospital, Toledo, Ohio, has come to lengthen the list of hospitals with hospital-operated "American"-equipped laundries.

Interior of the Flower Hospital laundry washroom, showing Underdriven Extractor and Cascades

Another view of the laundry, showing Flat Work Ironer.

Nor is it surprising that modern hospitals generally are turning to the hospital-operated laundry. The work is handled according to the hospital's own standards—laundry workers are directly responsible to the hospital management—hospital work always has the right of way—and it is not necessary to keep on hand such large stocks of linens.

As a forward-looking hospital superintendent, you are interested in the hospital-operated laundry. And it costs you nothing to confer with our corps of experts concerning any question of laundry installation or operation. We shall also gladly send you full information concerning the "American" installation at the Flower Hospital and at other well known hospitals throughout the United States.

HANOVIA
*Pioneer in
Quartz Light
Therapy*

FOR GENERAL OR LOCAL DERMATOPATHIA

Quartz Light Therapy plays an important part in the treating of Dermatological conditions, especially in Lupus, Psoriasis, Eczema, Pruritus, Acne, Infections, Nevus, Ulcers, and in those conditions where a strong bactericidal effect is indicated. The ultra violet rays are peculiarly adaptable for use either

as a local or general remedy, or both in the same instance.

The present ALPINE SUN LAMP is the mechanical perfection of those past HANOVIA LAMPS which have done so much to make available to the medical profession the therapeutic value of Quartz Light. It is a compact, efficient, and easily applied apparatus, having the entire quartz mercury anode type burner which insures the maximum intensity of rays, long life and a low operating cost.

The Operatometer

Each ALPINE SUN LAMP is now equipped with a simple but highly practical instrument, known as the OPERATOMETER. This device minimizes adjustments by automatically indicating when the lamp is at its most efficient operating intensity for effective therapeutic results.

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

BOOK REVIEWS

(Continued from Page 1642)

form. It is written in such simple language that no special training is needed to understand the contents.

The book is filled with descriptive illustrations and colored plates. The author has not only used his own collection, but has drawn freely from more extensive classics, such as Skillern, Politzer, Pratt, and Isaac Jones. While this volume is particularly well adapted for teaching the medical student and for use by the physician in general practice, yet it is so comprehensive and so full of the author's own refinements of technique that it is also a most valuable reference book for the ear, nose, and throat specialist.

A Christian Science practitioner is a person understood to be acting as a sort of interlocutor between God and the person "in error." This is the common understanding at least of the uninitiated. We have previously drawn attention in these columns to the fundamental psychology of optimism which, outside of the claims made for healing, seems to comprise the value of Christian Science. "Faith Healers" have for time immemorial embraced the psychology of suggestion in promoting their cures. Patent medicine advertisers take advantage of the same suggestive psychology to accomplish their ends. Electric pads, the gas-pipe frauds, as illustrated by the "Oxidonor" of local fame, the chiropractor, and innumerable other examples disclose the value of faith and suggestion.—Bulletin Wayne County Medical Society.

We hear much about the passing of the family doctor. Don't be alarmed. The passing of the slipshod, unscientific bunk dealer is a reality. But the well-trained, properly equipped, experienced general practitioner has a field today greater than ever before. He is a good diagnostician. He sees his patient as a whole. He knows his peculiarities and circumstances. He can decide when to refer him to a specialist and when to protect him from the danger which is threatened by a narrowly specialist point of view.—New York State Journal of Medicine.

A New

Vitalait Product

B. Acidophilus grown with lactose. An extremely high bacterial count is brought about by the addition of just the correct proportion of lactose.

Cultures are sent direct-by-mail to the patient. Information gladly supplied.

Wentz Multiple Wave Generator for Sinusoidal and Galvanic Therapy

A Point of View

The Victor X-Ray Corporation owes its leadership in the manufacture of X-ray and physiotherapeutic apparatus to a point of view.

This point of view recognizes the fact that roentgenology and physiotherapeutics are ever evolving new methods which must be reckoned with both by the physician and by the manufacturer of medical apparatus. But what new methods are sufficiently advanced for acceptance in practice the medical profession alone is competent to decide.

Hence, while the Victor X-Ray Corporation keeps abreast of the progress made by medical research it introduces only such apparatus as open-minded physicians are convinced they need.

Thus both medical progress and medical conservatism dictate the character of the roentgenological and physiotherapeutic apparatus developed by the Victor X-Ray Corporation.

"Of all human ambitions an open mind eagerly expectant of new discoveries and ready to remold convictions in the light of added knowledge and dispelled ignorances and misapprehensions, is the noblest and the most difficult to achieve."

—James Harvey Robinson in "The Humanizing of Knowledge"

Let us advise with you in the selection of X-ray equipment that best meets your individual requirements. PLANTS WHICH CAUSE HAYFEVER

UNDER the above title a new monograph — amply illustrated—has just been released from the press. The urge to prepare the booklet came directly from the physician himself who submitted first one question and then another and wrote from this or that section of the country and at all seasons. Therefore, in attempting to prepare a collective answer or rather a collection of answers, we were obliged to consider the sectional as well as the seasonal requirements throughout the land.

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

E. R. Squibb & Sons—Rabies Vaccine (Squibb), Simple method, fourteen-dose treatment.

Protein S. M. A. (Acidulated)—A modified milk preparation having a relatively high protein content and a relatively low carbohydrate content. Each 100 gm. contains approximately: Protein (of milk), 35 gm.; S. M. A. fat (consisting approximately of tallow oil, 0 to 10 per cent; coconut oil, 15 per cent; cocoa butter, 20 per cent; cod-liver oil, 7.5 to 12.5 per cent; tallow, 45 to 50 per cent), 22 gm.; carbohydrate (lactose), 28 gm.; ash, 6 gm.; moisture, 2 gm.; desiccated lemon juice, equivalent to 16.7 cc. of fresh juice. The content of lactic acid is regulated so that when the substance is diluted according to directions the liquid will have a pH of 4.6. The use of protein S. M. A. (acidulated) is proposed as a means of checking diarrhea, in malnutrition and marasmus, and in the feeding of prematurely born infants needing a high caloric intake. Laboratory Products Co., Cleveland.

Normal Horse Serum (New and Non-official Remedies, 1925, p. 329)—Marketed in packages of one syringe containing 10 cc.; also in packages of one vial containing 20 cc. Eli Lilly & Co., Indianapolis.

Pertussis Vaccine—A pertussis bacillus vaccine (New and Non-official Remedies, 1925, p. 353), marketed in packages of four 1 cc. vials; in single 5 cc. vial packages; in single 20 cc. vial packages; and in packages of four 1 cc. vials. Eli Lilly & Co., Indianapolis.

(Continued on Page 1662)

RIEBER

Every Doctor owes the help of this inexpensive X-Ray equipment to his patients

Have you ever wished for an X-Ray unit of your own?

One so simple to operate that your nurse could do it—easily.

One entirely self contained—free from overhead trolleys and wires—separate transformers and complicated control—

One so counterbalanced that you could tilt the table with the slightest pressure of the hand to any angle—

With a disappearing seat for examinations of children or where diagnosis demands a sitting posture—

A unit that gives you fluoroscopic vision of any part of the anat-

omy—or, instantly radiographic pictures, sharp and clear in focus.

The Rieber X-Ray Unit is such a device. More compact, less costly, easier to operate than any other X-Ray machine of comparable efficiency.

If you feel that such a device might prove a great asset to your practice—a great comfort and convenience for your patients—a great source of revenue for yourself, mail the coupon below for our illustrated brochure.

It contains twenty-four pages of complete information about the Rieber X-Ray Unit, and we'll gladly send it to you without any cost or obligation.

MINERAL WATERS

"Mineral waters possess no mysterious or occult virtues in the treatment of disease. No mineral water will be accepted by the medical profession for alleged medicinal properties supported only by testimonials from bucolic statesmen and romantic old ladies."

Prepared and Issued by the
PROPAGANDA DEPARTMENT
of the Journal of the American Medical Association
535 North Dearborn Street, Chicago

1923

2130

The above is a fac-simile of a pamphlet published by the A. M. A., containing important information regarding mineral waters; a copy should be in every physician's library. Upon request a copy will be sent, postpaid, to any physician. Address Bureau of Hygiene and Research, Box 10, Arcade Station, Los Angeles.

This page is published upon the authorization of the

BUREAU OF HYGIENE AND RESEARCH, PURITAS WATER DIVISION,
LOS ANGELES ICE AND COLD STORAGE COMPANY, LOS ANGELES.

Largest manufacturers and distributors of Distilled Water in the world.

Are You a Specialist?

Of course you are! You may be a "family doctor" of the good old variety—but nevertheless you are a specialist. You specialize in curing the physical [and sometimes mental] ills of humanity.

But the chances are you do not also specialize in business—investment securities—property values—collections and disbursements—the host of routine business details forced upon the attention of the professional man.

May we relieve you of the burden of those details? We are specialists. We can care for them at a lesser cost than you can yourself.

TRUTH ABOUT MEDICINES

(Continued from Page 1655)

Corpora Lutea Desiccated (P. D. & Co.)—The dried corpora lutea of cattle and swine. For a discussion of the actions and uses, see Ovary, New and Non-official Remedies, 1925, p. 251. The product is supplied in capsules containing five grains, and in tablets containing, respectively, two and five grains. Parke, Davis & Co., Detroit.

Streptococcus Vaccine (Lilly)—A streptococcus vaccine (New and Non-official Remedies, 1925, p. 359), marketed in single 5 cc. vial packages and in single 20 cc. vial packages. Eli Lilly & Co., Indianapolis.

Staphylococcus Vaccine (Lilly)—A staphylococcus vaccine (New and Non-official Remedies, 1925, p. 357), marketed in single 5 cc. packages and in single 20 cc. packages. Eli Lilly & Co., Indianapolis.

Staphylococcus Aureus Vaccine (Lilly)—A staphylococcus vaccine (New and Non-official Remedies, 1925, p. 357), marketed in single 5 cc. vial packages and in single 20 cc. packages. Eli Lilly & Co., Indianapolis.

Anti-streptococcus Vaccine (Lilly)—An anti-streptococcus vaccine (New and Non-official Remedies, 1925, p. 339), marketed in packages of one syringe containing 10 cc.; in packages of one syringe containing 20 cc.; in packages of one vial containing 10 cc.; and in packages of one double-ended vial containing 30 cc. Eli Lilly & Co., Indianapolis.

Pneumococcus Vaccine, Prophylactic (Lilly)—A pneumococcus vaccine (New and Non-official Remedies, 1925, p. 355), marketed in single 5 cc. vial packages. Eli Lilly & Co., Indianapolis.

Vaccine Virus (Lilly)—A vaccine virus (New and Non-official Remedies, 1925, p. 341), marketed in packages of one capillary tube and in packages of five capillary tubes. Eli Lilly & Co., Indianapolis.

Rabies Vaccine (Semple Method) (Squibb)—An anti-rabic vaccine (New and Non-official Remedies, 1925, p. 342) prepared according to the general method of David Semple (phenol killed). It is marketed in packages of fourteen syringes. E. R. Squibb & Sons, New York.

SANTA BARBARA COTTAGE HOSPITAL

"A Splendid Hospital in an Ideal Location"

Location—Santa Barbara, California, where ocean and mountains meet. Climatic conditions are perfect.

Metabolic Department—Diabetes and Metabolic Diseases are made a specialty.

Roentgen and Radium Department—Complete equipment for treating any malignant or non-malignant condition.

Cardiac Department—The equipment of this department, as well as the location of the hospital, makes conditions excellent for patients suffering from cardiac disturbances.

School of Nursing—The diversity of the work done by the hospital offers exceptional inducements to the prospective student. The Louise Savage Knapp Hall for Nurses, where the students live, is not surpassed in California.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Why Prescribe It for Infants Deprived of Breast Milk?

Synthetic Milk Adapted
to Breast Milk

1. **It gives excellent nutritional results in most cases.** That is the experience of thousands of physicians.
2. **No modification is necessary for normal, full term infants**—it is possible to give it, in the same strength, to infants from birth to two years of age. Only the total quantity is increased, as the infant's caloric requirements increase.
3. **It prevents rickets and spasmophilia**—the S. M. A. fat contains an adequate amount of cod liver oil. In addition, the kind of food constituents and their correlation in S. M. A. also play a role in the prevention of rickets and spasmophilia.
4. **It is easy for the physician to prescribe**—no complicated formulae to remember.
5. **It is simple for the mother to prepare**—just add boiled water.

We believe that once you have tried S. M. A. you will fully appreciate these advantages. Write for literature and a liberal trial package.
